Eighty mtrs in the summer is not the greatest band to try for comparisons but the stations I work on regular basis seem to have stronger signals and stay longer after sunrise.

An added benefit is having less wire and fewer supports to suffer from high wind effect.

1347. 4:1 Balun vs. Balanced Line Tuner

Yahoo group: SkyWires
Date: 2005-11-20 23:05:01 UTC
From: Marc Chappelle
Topic: 1347 Message: 1347

Hello,

With present band conditions being as poor as they are, I'd like to squeeze as much performance as possible out of my 40 meter delta loop. My loop is fed with 450 ohm ladder line running directly through the wall of the shack and into my MFJ autotuner. I'm able to tune most bands with the rig's internal ATU, so I really only use the external tuner for it's 4:1 current balun.

My question:
How much of a performance boost can I expect if I substitute the 4:1 balun with a real Balanced Line Tuner. I've read the various QST articles about the merits of BLTs over baluns, but what I'd really like to hear are some real-world experiences from people who've made the switch and whether or not there's any real discernable improvement.

Thanks
KA3ARF - Marc

If your feed line is properly balanced when using your 4:1 Balun and there is little loss through your MFJ antenna tuner then you would not see any difference when switching to a balanced antenna tuner. If however, your Balun is not operating properly or the antenna tuner has considerable loss through it then a properly tuned balanced tuner would make a huge difference. Check out this article as it goes into great detail on how to test and setup your antenna tuner and check the Balun for proper operation.

1350. 20, 15 & 10M Loop Antenna Project

Yahoo group: SkyWires
Date: 2005-11-25 23:56:11 UTC
From: SNKDavis@aol.com
Topic: 1350 Message: 1350
Attachments: 1 described; binary payloads are missing from this source WARC

Hi All,

I'm new to the group and thought that I would share my recent experience with a very successful HF loop antenna project. I have a Mosley TA33 Jr. for 20, 15 and 10, but due to neighborhood considerations it is only up about 17'. On 20M it works better than a dipole, but not nearly as well as it used to work on our 40' tower at our former QTH. At 17', the beam is not adequate on 20M for contesting and busting the DX pileups.

At the urging of some local hams, and knowing that I could put the antenna much higher in the woods, I decided to experiment with a full wave loop antenna. The antenna is vertical, hanging by a single line (thanks to Easy Hang) and supported by PVC:

The antenna is working great! When I switch from the beam to the loop, the spectrum display on the Pro II immediately pops up. Even with the beam directly on the station, the loop is superior. With the loops (and dipoles for 40 and 80), we were able to work 79 of the 80 sections in both Sweepstakes contests running 100 watts (missed ND for CW and NT for phone).

The 20M element is also resonant at the bottom end of 10M (SWR is flat at 28 and below 2/1 up to 28.6), so you get two bands with one wire. The loop is very broadbanded and a tuner is not required. Another plus is that the antenna is cheap to make. I used 3/4" PVC for the supports. The total cost for the PVC and cement was about $14.00.

If you want to try your hand at a loop, here are the details on how I constructed mine. These measurements are for 20M. Repeat using a 15M frequency for the 15M band. I have a simple Excel spreadsheet that will calculate all the measurements for any frequency, and I'll be glad to send it along if anyone would like:

1. Find the size of the loop by dividing 1005 by the frequency in MHz:

1005 / 14.175 = 70.9 feet. Go ahead and cut your wire.

2. Divide the length by 4 to determine the length of each side:

70.9 / 4 = 17.725

3. Since the PVC supports go to opposite corners, the supports must be longer than the sides. To determine the length, multiply by 1.4.

17.725 X 1.4 = 24.82 (length of PVC - corner to corner)

4. You'll need the following PVC parts:

5 - 10' X 1/2" PVC
1 - 4 way connector for the center
4 sleeves

5. Cut 1 of the PVC pieces into 4, 2.5 foot lengths

6. Assemble the PVC support

7. Lay your wire out on the structure, temporarily taping it to find where it should pass through the PVC

8. Drill holes for the wire through the PVC. After you run the wire through, wrap a bit of electrical tape on both sides of the wire next to the PVC to keep the wire from sliding and to give the PVC additional support. When hanging, the wire actually supports the horizontal PVC piece and keeps it from drooping.

9. Connect your coax. You can either solder the shield to one side of the wire and the center to the other or use an SO 239 dipole connector. I opted for the SO 239 connector.

10. A loop antenna is about 100 ohms. Sure enough, when I connected 50 ohm cable, the SWR was about 2 across the whole band. (100 / 50 = 2). For a better match, use a piece of 75 ohm cable (RG 59) as a transformer. Calculate the length as follows: 492 / frequency in MHz / 2 X velocity factor.

Assuming the velocity factor is .66, the calculation for 20M would be 492 / 14.175 / 2 X .66 = 11.45 feet. I had no idea what the velocity factor was for the RG 59 cable I had. A search on the web revealed most cables were between .66 and .8. One of the pieces I had was about 12 feet long, so I just went ahead and put connectors on it. The SWR results:

14.005 - 1.4
14.100 - 1.3
14.200 - 1.2
14.300 - 1.2
14.345 - 1.1

The antenna already has a good SWR across the whole band! If I was going for perfection, it looks like the antenna should be slightly bigger. The antenna could also probably be tuned by lengthening or shortening the RG 59 section.

Conclusion:

This is the first antenna project in a LONG time that has worked "as advertised" without lots of pruning, etc. I am really pleased with the results on 20, 15 and 10, and I'm considering adding additional loops on the same PVC structure for 17, 12 and 6. If I do, each will be fed with individual feed lines.

I hope that if nothing else, my weekend project fueled your imagination for some antenna projects at your QTH!

Comments, questions and suggestions are all welcome.

Hi Charles,

Thanks for your interest. The best view is really the diagram that I included in my first e-mail, and I'm providing it again here:

The picture came through fine here, but I know from experience on other lists that some have trouble viewing pictures from the reflector. If you can't see the above image, I'll be glad to send you an e-mail directly. Just let me know.

I spray painted the 3/4" PVC brown. It is tough to see hanging from the tree and VERY neighborhood friendly, but that limits the photo opportunities. There really is very little to the physical construction of the antenna. It is just a matter of cutting the wire to the proper length, drilling a few holes in PVC and soldering the SO 239 connector or coax end to the wire. I'll be happy to clarify any of the steps if you need more information.

By the way, in reviewing my e-mail I noticed that in the steps I had included 1/2" PVC in the parts list. I did try 1/2", but it tended to bow like a kite. I swapped the PVC out with 3/4". It still has quite a bit of flex on the ground, but it is hanging real well.

1353. Full Wave Loop

Yahoo group: SkyWires
Date: 2005-11-26 15:33:16 UTC
From: Thomas Giella KN4LF
Topic: 1353 Message: 1353
Attachments: 2 described; binary payloads are missing from this source WARC

If I may add, the correct formula for a single full wave loop is 1032 not 1005, 1032 comes from W4RNL the antenna expert. 1005 is used for cubical quad beams only.

I realize that I'm probably preaching to the choir but my personal experience experimenting with full wave loop antennas demonstrates that they are excellent on transmit and receive whether mounted vertically or horizontally. I'm using a full wave loop for 80 meters in the horizontal plane mounted at 35 feet and I work lot's of DX with it using just 125 watts. It's 288 feet long and 72 feet per side and I feed it on a side with 110 feet of 450 ohm window line and work through 10 meters with it.

The antenna has lot's of gain on the higher bands yest is fairly omnidirectional. Thse modeling figures are from W4RNL:

1 wl loop (70'/side), corner-fed: #12 copper 35' up over medium earth:
Freq. TO angle Max Gain Feed Z Pattern notes
MHz degrees dBi R+/-jX
3.58 90 5.16@45 67 +j 4 oval thru corners
7.1 48 5.69 84 -j150 oval across corners
10.1 41 9.32 370 -j575 narrow oval thru corners
14.1 27 10.51 305 -j105 clover leaves thru corners
18.1 20 13.75 350 +j240 EDZ-like thru corners
21.1 17 13.63 245 -j105 clover
24.95 14 14.09 320 +j110 thru crnrs w/side lobes
28.1 12 12.92 225 -j145 12 lobes

1 wl loop (70'/side, side-fed:) #12 copper 35' up over medium earth:
Freq. TO angle Max Gain Feed Z Pattern notes
MHz degrees dBi R+/-jX
3.58 90 5.09@45 65 +j 4 oval thru sides
7.1 44 6.73 275 +j130 oval thru sides
10.1 35 6.86 285 -j535 lobes at corners
14.1 27 9.69 265 -j165 4 lobes at corners
18.1 21 11.65 400 +j180 6 lobes, strong=far side
21.1 18 10.61 400 -j120 many lobes, strng=far side
24.95 15 11.08 370 +j 45 many lobes, strng=far side
28.1 11 11.83 250 -j180 many lobes, strng=far side
Here are a few links to W4RNL's articles on full wave loops:

http://www.cebik.com/wire/hl.html
http://www.cebik.com/fdim/atl1.html
http://www.cebik.com/wire/horloop.html

Though the TOA of the main lobe on a horizontal full wave loop is 90 degrees no matter the mounting height, there is a second lobe at 45 degrees about 2 db down that allows one to work DX. Last week I worked EI9HW on 80 meters phone using just 125 watts and I actually

broke the pileup on the first call to snag him.

My next project is to convert the 80 meter full wave loop to a 160 meter version.

Scott,

Looks like a really nice antenna. Im am a Amature radio operator and I am going to try to upgrade my license to Extra later on. Joined the group to learn more about antennas. Is there any way you could shoot some pictures of the antenna this way to me so I can look at how you made the antenna and how all the coax hooks up? This may give me ideas later on when I get to try my hand at homebrewing one.

Email pics to me at: harrell@inteliport.com

Thanks,

Joey

1. Find the size of the loop by dividing 1005 by the frequency in MHz:

1005 / 14.175 = 70.9 feet. Go ahead and cut your wire.

2. Divide the length by 4 to determine the length of each side:

70.9 / 4 = 17.725

3. Since the PVC supports go to opposite corners, the supports must be
longer than the sides. To determine the length, multiply by 1.4.

17.725 X 1.4 = 24.82 (length of PVC - corner to corner)

4. You'll need the following PVC parts:

5 - 10' X 3/4" PVC

1 - 4 way connector for the center

4 sleeves

5. Cut 1 of the PVC pieces into 4, 2.5 foot lengths

6. Assemble the PVC support

7. Lay your wire out on the structure, temporarily taping it to find where it should pass through the PVC

8. Drill holes for the wire through the PVC. After you run the wire through, wrap a bit of electrical tape on both sides of the wire next to the PVC to keep the wire from sliding and to give the PVC additional support. When hanging, the wire actually supports the horizontal PVC piece and keeps it from drooping.

9. Connect your coax. You can either solder the shield to one side of the wire and the center to the other or use an SO 239 dipole connector. I opted for the SO 239 connector.

10. A loop antenna is about 100 ohms. Sure enough, when I connected 50 ohm cable, the SWR was about 2 across the whole band. (100 / 50 = 2). For a better match, use a piece of 75 ohm cable (RG 59) as a transformer. Calculate the length as follows: 492 / frequency in MHz / 2 X velocity factor.

Assuming the velocity factor is .66, the calculation for 20M would be 492 / 14.175 / 2 X .66 = 11.45 feet. I had no idea what the velocity factor was for the RG 59 cable I had. A search on the web revealed most cables were between .66 and .8. One of the pieces I had was about 12 feet long, so I just went ahead and put connectors on it. The SWR results:

14.005 - 1.4

14.100 - 1.3

14.200 - 1.2

14.300 - 1.2

14.345 - 1.1

The antenna already has a good SWR across the whole band! If I was going for perfection, it looks like the antenna should be slightly bigger. The antenna could also probably be tuned by lengthening or shortening the RG 59 section.

Conclusion:

This is the first antenna project in a LONG time that has worked "as advertised" without lots of pruning, etc. I am really pleased with the results on 20, 15 and 10, and I'm considering adding additional loops on the same PVC structure for 17, 12 and 6. If I do, each will be fed with individual feed lines.

I hope that if nothing else, my weekend project fueled your imagination for some antenna projects at your QTH!

Comments, questions and suggestions are all welcome.

Scott,

Looks like a really nice antenna. Im am a Amature radio operator and I am going to try to upgrade my license to Extra later on. Joined the group to learn more about antennas. Is there any way you could shoot some pictures of the antenna this way to me so I can look at how you made the antenna and how all the coax hooks up? This may give me ideas later on when I get to try my hand at homebrewing one.

Email pics to me at: harrell@...

Thanks,

Joey

Hi Charles,

Thanks for your interest. The best view is really the diagram that I included in my first e-mail, and I'm providing it again here:

The picture came through fine here, but I know from experience on other lists that some have trouble viewing pictures from the reflector. If you can't see the above image, I'll be glad to send you an e-mail directly. Just let me know.

I spray painted the 3/4" PVC brown. It is tough to see hanging from the tree and VERY neighborhood friendly, but that limits the photo opportunities. There really is very little to the physical construction of the antenna. It is just a matter of cutting the wire to the proper length, drilling a few holes in PVC and soldering the SO 239 connector or coax end to the wire. I'll be happy to clarify any of the steps if you need more information.

By the way, in reviewing my e-mail I noticed that in the steps I had included 1/2" PVC in the parts list. I did try 1/2", but it tended to bow like a kite. I swapped the PVC out with 3/4". It still has quite a bit of flex on the ground, but it is hanging real well.

If you want to try your hand at a loop, here are the details on how I constructed mine. These measurements are for 20M. Repeat using a 15M frequency for the 15M band. I have a simple Excel spreadsheet that will calculate all the measurements for any frequency, and I'll be glad to send it along if anyone would like:

1. Find the size of the loop by dividing 1005 by the frequency in MHz:

1005 / 14.175 = 70.9 feet. Go ahead and cut your wire.

2. Divide the length by 4 to determine the length of each side:

70.9 / 4 = 17.725

3. Since the PVC supports go to opposite corners, the supports must be longer than the sides. To determine the length, multiply by 1.4.

17.725 X 1.4 = 24.82 (length of PVC - corner to corner)

4. You'll need the following PVC parts:

5 - 10' X 3/4" PVC

1 - 4 way connector for the center

4 sleeves

5. Cut 1 of the PVC pieces into 4, 2.5 foot lengths

6. Assemble the PVC support

7. Lay your wire out on the structure, temporarily taping it to find where it should pass through the PVC

8. Drill holes for the wire through the PVC. After you run the wire through, wrap a bit of electrical tape on both sides of the wire next to the PVC to keep the wire from sliding and to give the PVC additional support. When hanging, the wire actually supports the horizontal PVC piece and keeps it from drooping.

Hi Robin,

Thanks for your e-mail. I've received a lot of interest in this antenna! I'm glad, because it really is a great performer.

I'm going to try sending the picture as an attachment via the reflector so that it is available to others as well. I'll also send the Excel spreadsheet as a separate e-mail through the reflector. If they don't come through, please e-mail me directly at _snkdavis@..._ (mailto:snkdavis@...) and I'll be glad to send them again.

I've received several questions directly on attaching the coax to the loop. You can either use an insulator and solder the center of the coax to one side and the shield to the other, or you can use an SO239 connector. I like using the SO239 connectors. They only add a few bucks to the project and make a much neater and stronger connection. It also makes it a snap to swap out coax when needed.

Here is what I use for the loops (and also dipoles that aren't center supported):

802 CQ dipole, sloper, SO239, heavy duty, antenna supported. $8.50 Each

And for dipoles and Vees that are center supported, use:

801 CQ dipole center, SO239, center hang, heavy duty, UV resistant. $8.95 Each

The only difference between the two is the screw eye in the center of item 801. I order mine from The Wireman:

http://thewireman.com/antacc.html (http://thewireman.com/antacc.html)

Please post any questions that you have through the reflector and I'll be happy to help in any way that I can.

1358. my loop

Yahoo group: SkyWires
Date: 2005-12-04 23:00:06 UTC
From: m1azf
Topic: 1358 Message: 1358

firstly hi to all im new....
i have put a loop up in my garden and have fed it with 50ohm coax looking on many sites it was suggested curling the coax up about 8 loops to make a balun will i get better results just feeding straight with coax without the loop also i have found it works very well on 17metres not sure of the size but its triangle in shape i think its about 35ft by 35feet by 20 feet this is about all i can get in the garden not sure how to find out what band its most resonant on but i get about 1.7to 1 swr on most bands but 1.1 if i use the mfj tuner its only at 20 feet at present but hoping to raise it to about 38feet sloping to the house roof top it seems to work well into the states compared to my dipole will i find much difference when i raise it im also havent earth roded my station as yet will the earth stake make much difference to the performance also can i im prove what i have already got i know its small but is the best i can do with the resources i have to hand

im not to bright when it comes to theory as you can guess from my post but any help to make antenna perform better will be appreciated

many thanks shaun m1azf

1359. Re: [SkyWires] my loop

Topic: 1358 Message: 1359

At 11:00 PM 12/4/2005 +0000, you wrote:
>firstly hi to all im new....
>i have put a loop up in my garden and have fed it with 50ohm coax
>looking on many sites it was suggested curling the coax up about 8
>loops to make a balun will i get better results just feeding
>straight with coax without the loop

The loop you are describing is not a part of the antenna but serves as an RF choke to limit current flow on the outside of the coax feed line. It will only be effective at 11 MHZ, the resonant frequency of your loop. Feeding the loop with coax will only allow you to use it on the resonant frequency. If you want to feed the loop on different frequencies you will be better off feeding it with some kind of balanced feed line.

>also i have found it works very
>well on 17metres not sure of the size but its triangle in shape i
>think its about 35ft by 35feet by 20 feet this is about all i can
>get in the garden not sure how to find out what band its most
>resonant on

The loop as you describe it is 90 ft in length. The formula for determining the loop circumference is 1004/F (in MHZ).
Working backward 90 ft should resonate at 11.1 MHZ

>but i get about 1.7to 1 swr on most bands but 1.1 if i
>use the mfj tuner its only at 20 feet at present but hoping to raise
>it to about 38feet sloping to the house roof top it seems to work
>well into the states compared to my dipole will i find much
>difference when i raise it

Feeding this loop with coax and tuning it with your antenna tuner will make a very inefficient antenna. If you substitute a balanced feed line and couple it to your antenna tuner with a balun ... your tuner may already have a balun in it ... you will get a tremendous increase in effectiveness with this antenna.

>im also havent earth roded my station as
>yet will the earth stake make much difference to the performance

There is nothing wrong with grounding your station. However as far as antenna performance is concerned there should be zero improvement as a loop is a balanced antenna and does not work against ground. However, since you are feeding it with coax off resonance your antenna may well be working against ground like a vertical ... eg your coax may be your antenna !!! then grounding the station will have effect.

In summary:

In order to use your loop (as a loop) more effectively you basically have 2 alternatives. 1. Use the formula 1004/F (in MHZ) to make the length of the wire resonant to one amateur band that is close to what you have. For example if you add a few feet you will be resonant at 10 MHZ. You can then feed it with your coax feed line. However you will be limited to 10 MHZ.

If you want to cover other bands you have another alternative. 2. remove the coax feed line and substitute a balanced feed line ... eg TV feed line or 450 feed line. When it comes into your shack couple it to your antenna tuner through the 4:1 balun in your MFJ tuner. Your 90 ft loop coupled this way should be effective on 10MHZ, and higher. It might even work on 40M.

Wrong, wrong, wrong, wrong......

The coax choke will do it's job on an extremely broad range of freqs, not just on the resonant freq of the loop.

It will work fine even using a tuner to match the antenna on non-resonant freqs.....

And the loop will work at the resonant freq and above using a tuner just fine..will work better if the loop is multiples of a wave-length on the freq it is being tuned on, but will still work as is.....

Coax can be used with no noticeable problems compared to balanced feedline.
There is no pressing need to switch to balanced feedline....it really comes do to what you want to use.

I have yet to figure out the phobia displayed by some about using coax. Coax will work just fine. It will eliminate problems when you you need to run near metal objects. There is no real problem with coax at all.....

Surely you're not proposing to use coax feed on all bands? If you feed a loop antenna resonant at 11 MHZ with coax and then use it on say 21 MHZ and tune it to with an antenna tuner then the whole thing becomes the antenna; the loop, the coax feed line, and all your connections to ground. The few turns at the feed point, the supposed RF choke, simply becomes a bit of inductance in the overall antenna. With this situation these turns at the feed point are irrelevant. now that is true, true, true (only 3 trues)

well at the present time i am able to work 40metres 20metres 17met
res 80 is oviously a no no okay so feed it with 450 0hm the only
thing im worried about if i feed with 450 ohm am i more likely to
cause tvi does it matter the length of this also if its slightly
sloping will it be slightly directive as opposed to the signal going
straight up. 17 metres seem the best band at present the figures i
gave are only an estamate could be a little bigger or a little
smaller i havent looked at ten or eleven as you think it might be
resonant on ill do a test now see how the swr is on these bands
ideally id like to make it work better for 20 upwards with posibilty
of 40 all this is a real learning curve for me thanks to all,.i was
told this antenna wouldn.t be any good for dx but the noise level
allows me to hear more anywaysas i was getting s7 noise levels with
the dipole and im now getting s2/3 on good days s5 on bad days i
couldnt believe the difference i just need tighter filters for my
icom 706 and i think its going to be like night and day the
differece that is if this is the antenna not working properly i cant
wait to feed it with 450 ohm as it already out performs my home made
dipole made from an recked g5rv..have just checked swr on 10megs its
1.21 bypassing the tuner this is on 10.400 megsso it got to be about
the size that was descussed earlier if i can get it out to a square
shape rather than triangle means adding another support this should
give me34x34x20x20 roughly 108 feet of wire with my calculations but
this is probably my max unless i can get it over the apex of the
house somehow ill have to think about that one...

ps thanks for the help so far

1363. RE: [SkyWires] my loop

Yahoo group: SkyWires

From: Paul MW0CDO
Topic: 1358 Message: 1363

I would second Mel's comments here.

I've been using a 40m loop in rectangular configuration supported by 4 20ft fishing poles for close on 2 years now.
My personal experience shows no problem with using coaxial cable to feed a loop.

The loop is constructed with 1mm diameter insulated wire.
Fundamental resonance is around 6.7MHz.
The dimensions are approx 15m (50ft) sides and 6m (20ft) ends.
There is a drawing and photo of the feed point at
http://radioham.spymac.net

I've fed this loop with 75, 300 and 450 ohm balanced feeder and tested with 2 different Pi network tuners, one homebrew and the other an MFJ 949e.
I could not get a good match on 80 or 160m using balanced feed.
As an experiment, I decided to hook some RG58 to the loop and test.
To my surprise I found the loop would now match on 80 and 160m with 5m (17ft) of RG58 feeding it.
Sure it's touchy to tune and an auto ATU probably wouldn't match it on 160 or even 80m but I can get it to play using either manual tuner.
Having established that it was possible to tune on 80 & 160m, I added an RF choke right at the feedpoint in an attempt to stop some of the RF in the shack. My shack is upstairs on the 1st floor and the loop passes by about 10ft from my operating position
The choke is an 8 inch long x 3/8 inch diameter ferrite rod stolen out of a 1960's portable radio.
I wound 15 turns of the RG58 feeder on the rod, this stopped a whole lot of problems.

So far I've worked 2000 miles on 160m with 100 watts feeding the ATU.
On 80m it works well into western europe for me, as well is inter UK contacts.
On 40m and above it works very well, not as good as a ground mounted Butternut HF6v on 10m DX though.

Don't be afraid to experiment.
Ignore what the text books tell you sometimes!
My feed arrangements are definitely not approved by most antenna books, yet it works very well.

Paul MW0CDO.

From: ve7agw
Topic: 1364 Message: 1364

I agree with Mel, I've run coax with 8 turns around a plastic coffee can to feed my 80 meter Delta Loop. And I could tune it from 80 to 6 meters with a 1.1 to 1 match using an Icom AT-180 tuner.
I later switched to a home-brew 4:1 balun and made the loop into a four side with coax running only about 20 feet to a remote balun then approx. 75 feet of good 300 ohm TV ladder line. And this made my loop very broad banded. I can now tune all the way from 160 to 54 mhz with the highest VSWR at 1.5:1 and most at 1.1:1.
I use the remote balun so as to keep the rf out of the shack but keep the losses from the feed line down as well. The coax balun worked great as well but I didn't want the feed line loses so I went to ladder line for the majority of the distance.
Like Mel says the balun will work very broad banded. I tried the Delta loop with just with just feeding it with coax with no wound coax loop at the feed point and it worked ok, but I had a hard time tuning it without getting rf feedback. By using the coax balun it kept the rf from feeding back down the ground side of the coax.
I've also found that having as good a grounding system also make a big difference with a loop too.

I think we all worry to much about RF radiation on a piece of coaxial cable feedline due to common mode currents. Often times radiation from the coax will fill in nulls that exist on the antenna, a good thing. But if you must a 1:1 balun made out of coax it will work pretty good. You just have to use the correct number of turns for the lowest band that you plan to operate on. Of course though there is the negative issue of picking up QRN on the coax cable feedline on receive without a balun too.

In my personal experience the chance for RF radiation of signal and pickup of QRN is greater with coaxial cable feedline than ladder or window feedline. Currents are more apt to be balanced or closely balanced on 300/450/600 ohm ladder or window line with less problems. And if you use a homebrew or store bought balanced link tuner then appreciable current imbalance is not going to happen.

Personally I think it's a bad idea to use a coaxial cable feedline on a loop antenna used for muliband use on even harmonics. The capacitive and inductive reactance (SWR) as well as voltage will be so high that huge signal losses will occur and the high voltage will eventually burn a hole through the coax. RF loss in ladder or window line is much less with a high VSWR than coaxial cable.

I have a full wave loop up for 160 meters fed with 110 feet of window line and I use it all the way up to 10 meters, using 5-100 watts of power with great success.

Just my .02.

If an antenna is fed properly there is no deed for an RF ground. If your set up requires or an RF ground it is simply a stop gap arrangement to offset poor design. I hear many people say ... heh I used 300 ft of wire strung over this tree and that roof and I worked 2000 miles .... any piece of wire will get out! If that's the discussion that is not antenna design discussion.

From: ve7agw
Topic: 1358 Message: 1369

Paul and the group,

There are so many variables when it comes to constructing an antenna that experimenting is the only practical means of making an antenna work or improve it's abilities.
What works for one location may not work at all for the next. Just by reading the last few days of the groups posting will show this. And then of course we throw in personal opinions and prospective and we have a good discussion going. Like Paul said, throw the text books out some times and try something new or unheard of, you never know what will happen till you try it. This is how my loop got built and it works like a charm, it even out performs my TA-33 on 20 meters most of the time. Some say that a loop is no good for DX, yet I've worked JA and HB's with my loop. At lot has to do with conditions and your location.
Personally I think a lot of antenna designs were found by accident. And the bottom line is "if it works don't fix it". what works for you may not work for your neighbor.

73...de ve7agw and Merry Christmas everyone. Here's a little poem I found that fits for us amateurs at Christmas.

Twas the night before Xmas
And all through the house
Everything was stirring
Even the mouse

Tranceivers were tuning
and aerials were up
the scotch was disguised
in a large plastic cup

Fingers on buttons
were starting to itch
this waiting on New Year
was becoming a bitch

But soon it came nearer
the party was nigh
dipoles and loops
were all hoisted high

Grins on all faces
this HF was great
No Morse to learn now
It had gone to its fate

The clocks being watched
ticked over so slow
one minute to midnight
one minute to go

And then right on time
came a signal so clear
they thought the transmitter
was terribly near

But they'd never forget
Oh that terrible sound
they were cursing and screaming
and running around

For out of the speaker
So crisp and so clear
Came the sound they abhorred
And had learned how to fear

And it said....

dahdah/dahdah/dit/ditdahdit/ditdahdit/dahdedahdah/
dahdididah/dahdah/didah/ditditdit

I would second Mel's comments here.

I've been using a 40m loop in rectangular configuration supported by 4 20ft fishing poles for close on 2 years now.
My personal experience shows no problem with using coaxial cable to feed a loop.

The loop is constructed with 1mm diameter insulated wire.
Fundamental resonance is around 6.7MHz.
The dimensions are approx 15m (50ft) sides and 6m (20ft) ends.
There is a drawing and photo of the feed point at
http://radioham.spymac.net

I've fed this loop with 75, 300 and 450 ohm balanced feeder and tested with 2 different Pi network tuners, one homebrew and the other an MFJ 949e.
I could not get a good match on 80 or 160m using balanced feed.
As an experiment, I decided to hook some RG58 to the loop and test.
To my surprise I found the loop would now match on 80 and 160m with 5m (17ft) of RG58 feeding it.
Sure it's touchy to tune and an auto ATU probably wouldn't match it on 160 or even 80m but I can get it to play using either manual tuner.
Having established that it was possible to tune on 80 & 160m, I added an RF choke right at the feedpoint in an attempt to stop some of the RF in the shack. My shack is upstairs on the 1st floor and the loop passes by about 10ft from my operating position
The choke is an 8 inch long x 3/8 inch diameter ferrite rod stolen out of a 1960's portable radio.
I wound 15 turns of the RG58 feeder on the rod, this stopped a whole lot of

problems.

So far I've worked 2000 miles on 160m with 100 watts feeding the ATU.
On 80m it works well into western europe for me, as well is inter UK contacts.
On 40m and above it works very well, not as good as a ground mounted Butternut HF6v on 10m DX though.

Don't be afraid to experiment.
Ignore what the text books tell you sometimes!
My feed arrangements are definitely not approved by most antenna books, yet it works very well.

Paul MW0CDO.

If that's the discussion that is not antenna design discussion.

Thomas KN4LF Says:
That's correct but there is an exception. If your radio shack is in the RF field of the antenna because it's to close then you can get RFI. My house is surrounded by my 160 meter full wave loop which is mounted at only 35 feet and supported at the four corners of my 1/2 acre of property.

So RFI becomes a problem for me on the digital modes only on 20-10 meters. However I tune 1/4 wave radials on these bands with the MFJ-931 and the RFI disappears.

HI Thomas,

Well I would consider your situation an example not an exception. If you build a loop around your shack you may well need to have tuned radials to tame the RF at the rig .... if you want to keep that antenna design then that is a strategy you will have to use to offset the design.

73 and Season's greetings to you as well

If you place one choke balun at the antenna feedpoint and a second one just outside the radio shack cable entrance it will really knock down QRN on receive due to common mode currents. It's also best to make your choke balun out of coax with a solid center not foam like RG-8X has, because the foam allows the center conductor to migrate out of alignment with time.

73 & Merry Christmas,
Thomas F. Giella, KN4LF

I recently bought some RG-8X made specifically for Marine Mobiles for exactly that reason.It has a solid polyetheline center insulator and can supposedly be walked on without harm as well as having less tendency toward center conductor migration in bends. I don't intend to subject it to much of either type of trauma but thought it might be tougher than the standard RG-8X. Price wasn't much different.

You are confused about grounding. In most locations there are 3 kinds of ground. Your electrical supplier will have a ground system according to the electrical code in your location. This ground will be tied into to electrical supply and the panel at your location and they will install the required ground rod etc.. Then, as a radio operator with various antennas which are always in danger of lightning or static build up you will take precautions to reduce these dangers, eg lighting arrestors, and antenna grounding switches etc ....

Then there is the third type of ground .... RF ground ... which is related to your antenna characteristics and how it interfaces with your transmitter. This has nothing to do with the first 2 safety type grounds. A well designed antenna/feed system does not need an RF ground.

I don't remember if those are the ones with the sleeve capacitors or not. Anyhow, best to disassemble and clean out the telescoping sleeves and clean and tighten the coil screws which are surely corroded a bit ... they always are. The last one I did was reassembled with non-conductive silicone grease to retard the corrosion process.
I used an MFJ analyzer to retune (10' of mast tied to a wooden step ladder). When it was back up on the tower, the SWR dipped nicely where it should.
Hope this helps,
Bob, N1KPR

Mike,

Yes go with the 450 ohm window line versus the 300 ohm. The further apart the two parallel wires are with less insulating material in between, the less loss you have in the feedline under high VSWR conditions. Also the feedline reacts less impedance change wise to moisture and dirt build up.

Gee Whiz... Hmmmm... 4500 Ohm feed line...

Now, I am a rookie at all this, but I suspect this
would pretty much kill the entire project...

(Yeah... I know it is a typo... but I just cannot
resist poking some fun atcha.)

Happy trails. and... maybe Santa will bring you
a nice new rig.

I disagree--- in fun of course... but I figure there is
at least ONE EXCEPTION :

For every case of unexpected "found money" (i.e., bonus,
gift, prize win... etc.)...

... the recipient or finder encounters a larger,
UNequal cost calamity or expense to eat it up...
and more!

That is why I do not want to win the Lotto... it would
certainly be followed by some sort of financial disaster
of truly epic proportions!

Just my cynical take... Happy trails to ya all.

1394. Coax Fed 450ohm Ladder Line?

Yahoo group: SkyWires
Date: 2005-12-15 15:18:25 UTC
From: JD WG5B
Topic: 1394 Message: 1394

Hello everyone and Merry Christmas and Happy New Year! This is my 1st of hopefully many post's!
I am in the process of putting up a full wave 160 meter loop, it will average about 30' above the ground, and since I am using existing trees on my property to support it, technically it will probably be a delta loop, as my trees did not do as instructed and grow in a perfect square! (Yes I am very disappointed with them! But they are mine what can I do?) :-)

My questions is, as I am feeding this with 450 ohm ladder line, and have no way to get the ladder line through the wall to my rig without modifications to the house, (not going to happen!) I was told by an old timer to feed it with 20' 4" of coax and the Coax will act as the Balun and allow me to bring it in to my tuner? Any thought's or suggestions please? Thank's 73 JD

Nits!! You should be able to feed the ladder line into
your home without too much trouble. Under a window is the
easiest - or inside a door frame. Or sneak it under the siding
between the foundation and the sill joist or the sill plate
(I can get coax in between mine if I work at it...) or see
the window block pass through on this URL:

Ladder line needs just a small slit of space to get into the home...
you gotta be able to figure a way for that to work. Homes are
not that well sealed off in all ways... Fee it up into the attic
via a vent or snake between the siding into the attic (there IS
a way on every home...) and bring it down through a closet
to your rig.

Just my take. Your mileage may vary...

For my 80 meter loop I simply go from 450 ohm line to coax to a
RadioWorks Line Isolator
to coax into the shack to a tuner. I do mostly the same for a 40
meter GP vertical. I use the line
isolator to keep the rf out of the shack. It was the solution to my
particular rf problem.

The loop is low (a cloud burner supposedly) but I am able to work the
east coast barefoot from San Diego on 80 fairly easily so I am happy
with the performance.

Just fyi.

Are you going to use the full wave loop only on 160 meters? If so the coax balun will probably work pretty good if you have an antenna analyzer to design the balun in an electrically correct manner. If you are going to go for multiple band operation I would bring the window line in to a homebrewed balanced L network or link coupled balanced tuner. Even a tee network tuner with a 4:1 balun on the high side will work better than a coaxial balun for multiband use.

I have always brought my antennas and station ground into the shack via a piece of Plexiglas in the window. Works good with no holes in the wall.

Using coaxial cable as a balun has been used successfully for decades. Look in any ARRL antenna handbook for examples.

You have a usable horizontally polarized signal at 3 db down with a TOA of approximately 52 deg. You also have a usable vertically polarized signal at 6 db down with a TOA of approximately 50 deg. That's why the 90 deg. TOA alleged NVIS cloud warmer only full wave loop works contacts out to 2000-3000 miles!

JD,
I would feed it with 450 ohm ladder line from the antenna to just outside the shack then use a 4:1 balun and go from it into the window with a few feet of RG-8 coax to the rig or antenna tuner.

I show how to homebrew a 4:1 balun at

http://www.bloomington.in.us/~wh2t/balun.html

Also,
Here's an alternate method I have used in the past to run coax thru a double sash window. It works great if you are only using one coax or up to a few coaxes.
Start with the window(s) closed. For each RG-8 type coax drill a vertical 7/16 inch hole thru the seam where the upper and lower sashes meet (to the distant left or right of the center window lock). Don't go all the way to the left or right side of the window. The drill bit should be in front of the glass when you start drilling.

Half of the hole will be drilled thru the bottom of the top sash. And the other half of the hole will be drilled thru the top of the bottom sash.

Now with the window open, from outside the house, push the end of the coax up thru the vertical hole (the PL-259 will fit thru also as long as the window is open). After you get enough of the coax in the house to meet your need, close the window. It will form a seal around the coax, and since the coax runs up thru the hole no water can drip in.

If the hole(s) is temporarily not in use, you can put a cork stopper in it (corks are available at hardware stores). If you decide to repair the hole(s) because you are moving, selling, renting the house etc. Wood putty should be an easy fix. Plus the empty vertical holes are much more difficult to notice than horizontal holes.

Just my 2 cents. Ace - WH2T

Subject: [SkyWires] Coax Fed 450ohm Ladder Line?

Hello everyone and Merry Christmas and Happy New Year! This is my 1st of
hopefully many post's!
I am in the process of putting up a full wave 160 meter loop, it will
average about 30' above the ground, and since I am using existing trees
on my property to support it, technically it will probably be a delta
loop, as my trees did not do as instructed and grow in a perfect square!
(Yes I am very disappointed with them! But they are mine what can I do?)
:-)

My questions is, as I am feeding this with 450 ohm ladder line, and have no way to get the ladder line through the wall to my rig without modifications to the house, (not going to happen!) I was told by an old timer to feed it with 20' 4" of coax and the Coax will act as the Balun and allow me to bring it in to my tuner? Any thought's or suggestions please? Thank's 73 JD

1406. RE: loop -> 450 vs. 300 ohm

Yahoo group: SkyWires
Date: 2005-12-15 23:47:50 UTC
From: Ron McConnell
Topic: 1406 Message: 1406

Thomas Giella KN4LF" <flcyclone@...> says
"Yes go with the 450 ohm window line versus the 300 ohm."
and gives good reasons for that.
In addition, TV grade 300 ohm line is relatively
flimsy with fine gauge wire compared
to good 450 ohm ladder line.

Playing around on the Smith chart and with
t-line programs suggest that a t-line impedance
between 200 and 300 ohms is better range
for the wide range of antenna impedances
(a few ohms to a few thousand ohms)
encountered with center-fed or end-fed doublets
for multiband use. 450 ohms is near the upper
limit for getting a good range as seen
at the transmitter end.

See Gary N3GO O'Neill's article
from Communications Quarterly, Fall 1996,
"From a J to a Zepp
The truth and its consequences"

<http://snow.prohosting.com/~w0rcy/Jpole/jpole.html>
and
<http://webpages.charter.net/aa5tb/efha.html>

Does anyone make good 300 ohm ladder line?
[Gotta do a search.]

Technically you are correct it is not a "balun" after reading some suggested websites it is actually more of a "Transformer" and by all examples and statements it apparently works extreemly well!!

My XYL gave in! I had her read several of the replies and explained to her exactly what I had in mind, which was to use a 3 1/2" hole saw to cut a hole through the wall directly under my opoerating position (out of sight inside) and insert a peice of 3" schedule 40 pvc pipe through the hole, then drill or cut holes to fit the wire/coax in 2, 3" pipe caps (one inside one outside) run them through push on pipe caps (they fit tight enough to seal without screws or anything else) seal around coax or ladderline holes with caulking... as I said she said ok and it is done! She said ok I did not give her a chance to change her mind! I installed it all this afternoon... Feeding ladderline directly with my Tentec Model 238 tuner, Works Great!. 73 JD

a coil of coax is not a balun.....its a choke....which is common to use on antennas to choke rf so it wont come
down the coax any further.....a balun is a device wound on a core consisting of two windings of different wires.

the new clamp on chokes from amadon and other sources will do a better job of surpressing rf then a coil
of coax will, as the coax winding is for a given frequency...whereas the clamp on chokes cover the whole
hf spectrum....

The coax choke is not for a single freq....it works equally well on freqs well above the 'design freq'....

Example....the coax choke on my 80mtr crossed dipoles works great to keep the RF off the braid on 80...as well as 40, 20, 15, and 10.....all bands I used to have RFI problems trying to tune....

Hardly a single band design.......

Yahoo group: SkyWires
Date: 2005-12-16 06:04:22 UTC
From: oh6bi
Topic: 1414 Message: 1414

Hi All!

I am New in this group and it is good to tell something about me:
Name is Rami, first licence 1980 and qth is Vaasa 60,000 people town on the coast of the western Finland. I have two callsigns oh6bi (my first one) and 9j2bi when I am at my second home in Zambia. Zambian call I got 2002.

Here in Finland my home is in flat,top floor, balcony 13meter from the ground. In the balcony is my pizzabox,IC AH3 feeding 10m wire up to horisontal 41m long wire between two houses, totally antenna is 51m.
Horisontal part is abt 18 meters from ground in free space, just some flower bushes down there. This wire is quite good for all bands but I wish to have some gain for low bands. Now planning to put 160m loop instead of that wire. Distance between flats is abt 60m and they are similar, the maximum loop size in the open space could be abt 50x50m = 200m , enough space for 160m loop. Feeding will be done by ladder line from pizzabox.
My question is: What is the best feedpoint with 160 loop as thinking multiband operation, mainly 40m to 160m ?
(for higher bands I have wertical on the roof)

Best regards, 73s and gl dx de rami, oh6bi

I think you are referring to a "coax choke" which doesn't do what you suggest, but actually offers high reactance to common mode currents and "chokes" currents on the outer portion of the coax, moving in BOTH directions. No, choke coils are not for a "specific frequency." They are effective for any frequency above their lowest design frequency. They are chokes. They exhibit inductive reactance and follow the same laws of physics.

Your description of a balun is not accurate. I think you are thinking of the commercial term for those things found in PVC tubes and variously sold in the back of magazines. But there are many other forms of baluns. Any transformer that matches balanced to unbalanced transmission lines is a balun. A transformer does not need to have "coils of wire" to be a transformer -- nor a core. If impedance conversions are are achieved within a device, then it is a transformer. Tuners (Transmatches/couplers) are transformers. Coaxial cable which has been cut to the correct size and wired as a shorting stub is a transformer.

If you use clamp on ferrite beads to eliminate common mode currents on your coax, instead of a choke coil, check them under full power conditions, because under the right conditions, they can also choke-off differential currents present in the coax shield. That's not a good thing -- make sure they are not getting warm during use.
Bob

1416. 160 m Loop

Yahoo group: SkyWires
Date: 2005-12-16 15:23:36 UTC
From: ve7agw
Topic: 1414 Message: 1416

Hi to Finland and the group.

I feed my loop about the center of one of the flats on the four square, although I know of others who feed them at a corner and it works just as good. Feeding at a corner is fine as lone as the angel of the two wires is not lower than 45 degrees, other wise you will bet a feed back point that will throw you're an auto tuner into bypass. I found this one out the hard way took me over a week trouble shooting to find out that my tuner didn't like the feed point.

Basically, just run two lengths of coax side-by-side through the wall, with the shielding soldered together at each end. Inside hook up the station ground to the shielding (thus grounding both shieldings). The shielding's are only connected to each other (and the station ground inside your shack).

Treat the two center conductors as you would regular ladder line, except since they are shielded you can run them through wall, along metal, etc., without worry.

Outside just solder (or wire nut, etc.) the coax to the 450-Ohm ladder line.

The proper length of coax is whatever accomodates your needs. As with nearly any installation, if you are unable to tune your antenna, you can add or subtract about 1/8 to 1/4 wavelength of transmission line, or try a tuner of a different design or component size. But this is beginning to stray off subject.

If I recall correctly, the impedance of the coax ladderline will be twice the nominal impedance of the coax (e.g. 50-Ohm coax become 100-Ohm ladder line).

The ARRL Antenna Book describes this and has a table with a few examples.

>please? Thank's 73 JD

Hi JD,

I understand the problem .... 450 ohm ladder line is difficult to bring into the house. I don't know about the 20' 4" coax trick ... I would think that keeping the feed line balanced right from the antenna to the tuner would be the best bet. A trick I have used many times was to use 75 ohm balanced line (diameter approx the same as RG58). I used a piece of sufficient length to get through the wall etc ... with 300 ohm line on the inside of the house and the 450 ohm line outside the house. So what you have is 300 ohm line from the tuner to the wall, 75 ohm line through the wall, and 450 ohm line from the wall to the antenna. Keep the higher loss balanced line short as possible.

The problem is that 75 ohm balanced line is now all but impossible to find. Beldon Cable used to make low and high power versions. It was great stuff for feeding dipoles and full size loops. Not too long ago I had this same situation and could not find 75 ohm balanced line (only need a few feet) .... and used 2 wire #16 power cord ... the kind you find in cheap extension cords (some times referred to as zip cord). It works fine. In fact I have used the same zip cord to feed a dipole directly for field day type operation. A resonant dipole is approximately 75 ohms. This antenna fed via zip cord to a 1:1 balun to the rig operates with less than 1.5:1 SWR. As a result I suspect that zip chord represents a feed line impedance of about 100 ohms.

Merry Christmas

JD (Jim Dunstan) hi

Tell the XYL I think that sounds like a capital solution - and if I
get the image correct in my head, it could be used for different
and additional lines in the future. At first, I wondered why you used
such a large diameter pipe, but I can see that you could install
additional coax lines cool wax lines through it in the future -- and
especially because you did not glue down the end caps.

I might just copy that design...
Best Regards. //// Richards ////

1421. 160m loop at higher bands ?

Yahoo group: SkyWires
Date: 2005-12-20 06:06:54 UTC
From: oh6bi
Topic: 1421 Message: 1421

Hi All !

Plannings for 160 loop are running here but
I have to stay on the plannings level until we get some
higher temperatures here; it is not very cold but
enaugh to prevent me to start wire works on the roof.
This morning my digimeter was showing minus 15 Celsius (5 F).

I had conversation with my friend (oh-ham) and he was telling
that 160m loop is not so good as 80m loop for 40m band.
He has done experiments some years ago and got better gsos at 40
when using 80m loop. How is it ??
I have seen many articles how 80m loop is running at higher bands
and I have tested 80m loops at my summer cottage with good results
but never built any loop for 160.
Anyone know good info how the height effects with loops and different
bands ? (maybe it is same as the other antennas ..)

This qth I am staying is giving good possibilities for 160m wire
experiments and I have to do it now, never know how is the next
home ...

The loop will be 18m (abt 60 ft) up from ground level, corner fed and
free space, distance to nearest building under antenna is abt 20m.
It came my mind also to put two loops there: 80m inside 160m ?
What you say about this idea ? can it work ? I have seen some wire
constructions for 20,15 and 10m, I think it was in the Moxon´s
antenna book. Comments ?

From: Thomas Giella KN4LF
Topic: 1422 Message: 1422
Attachments: 1 described; binary payloads are missing from this source WARC

On a 160 meter full wave loop the TOA on 40 meters will be approximately 35 deg. versus 44 deg. on an 80 meter full wave loop. So in theory you would be able to work more DX on 40 meters with the 160 meter loop versus the 80 meter loop.

If the critical frequency is above 40 meters then close in QSO's are going to occur too but not as many or as strong as say on an NVIS antenna with a 90 deg. TOA.

Rami,
A 160 mtr loop will not work as well on 80 mtr band as an 80 mtr loop.

Subject: [SkyWires] 160m loop at higher bands ?

Hi All !

Plannings for 160 loop are running here but
I have to stay on the plannings level until we get some
higher temperatures here; it is not very cold but
enaugh to prevent me to start wire works on the roof.
This morning my digimeter was showing minus 15 Celsius (5 F).

I had conversation with my friend (oh-ham) and he was telling
that 160m loop is not so good as 80m loop for 40m band.
He has done experiments some years ago and got better gsos at 40
when using 80m loop. How is it ??
I have seen many articles how 80m loop is running at higher bands
and I have tested 80m loops at my summer cottage with good results
but never built any loop for 160.
Anyone know good info how the height effects with loops and different
bands ? (maybe it is same as the other antennas ..)

This qth I am staying is giving good possibilities for 160m wire
experiments and I have to do it now, never know how is the next
home ...

The loop will be 18m (abt 60 ft) up from ground level, corner fed and
free space, distance to nearest building under antenna is abt 20m.
It came my mind also to put two loops there: 80m inside 160m ?
What you say about this idea ? can it work ? I have seen some wire
constructions for 20,15 and 10m, I think it was in the Moxon´s
antenna book. Comments ?

W2HT Said: A 160 mtr loop will not work as well on 80 mtr band as an 80 mtr loop.

KN4LF Says: With due respect I say Dr. Ace that's a bit of a broad statement, it all boils down to what you are trying to accomplish on 80 meters.

If you want to rag chew locally and regionally out to say approximately 500 miles, then the 90 deg. TOA of an 80 meter full wave loop is best. With the added bonus that EZENEC 4.0 modeling shows that the loop also has a secondary TOA of approximately 52 deg. 3 db down from the main 90 deg. TOA lobe, that will allow contacts out to approximately 2000 miles. My real world experience has allowed me to work the west coast of the U.S. from Florida with that TOA of 52 deg.

If you want to work DX with a loop on 80 meters then your choice would be the 160 meter full wave loop because the TOA on 80 meters is approximately 43 deg. and will allow for DX contacts out to approximately 10,000 miles. My real world experience has allowed me to work ZS6CCY on 80 meters with the 160 meter full wave loop from Florida, a path of approximately 8200 miles.

Where you can run into problems operating 80 meters on a full wave 160 meter loop is the fact that 80 meters is a even second harmonic on the 160 full wave loop, so you have high voltage at your antenna tuner and you can get arcing inside the tuner if you use the typical store bought tee network tuner with a 4:1 balun on the hot side, like an MFJ-989C, 949E, etc.

But if you homebrew a link coupled balanced tuner or balanced L network balanced tuner with large enough voltage and current capacity components then arcing is not an issue. This will allow you to work the world on 80 meters with a 160 meter full wave loop.

BTW I have done allot of antenna modeling using ELNEC/EZNEC during the past 8 years and have found that if you model the antenna correctly and can correctly interpret and understand what the model data is telling you, then you can pretty duplicate the modeling results on the air. However let me preface that statement by saying that I'm no antenna modeling expert like W4RNL.

Hello Thomas,
I know I made a broad statement and I figured someone would comment on it. I was in a hurry. I agree with everything you wrote. However, I think if a persons main objective is to work DX, that person could choose an antenna better suited for DX work than a horizontal loop.
I am not a big DXer, if I hear an interesting DX station I can usually succeed in working that station pile up or not. I have used a 160 mtr horizontal loop and an 80 mtr horizontal loop on 80 mtrs and other bands. From Indiana I have worked all 50 states many times over including Alaska and Hawaii a bunch of times on 80 mtrs using horizontal loop antennas. My main band of operation is the 80 mtr band. For myself I will stick with an 80 mtr horizontal loop on 80 mtrs.
BTW, I operate all bands from 2 thru 160 mtrs.
Happy Holidays and Merry Christmas to all.

Dr. Ace yes I know that you are very knowledgeable about antenna's and have allot of practical experience via experimentation. So no flame was intended and that's why I began my email with, "With due respect.....".

I was simply pointing out several options for a loop antenna for close in ragchewing and DXing based on my practical experience via experimentation.

BTW I'm a very spiritual person as you are.

i want a loop antenna for 75 meters...i can only put up one 200 feet square....could i at one side of the loop go back and forth with the wire to gain another 80 feet of wire to make a total length of 280 feet ? the antenna would be 20 off off the ground.

any input would be appreciated

bob

Bob,

I would think for 4.000 mhz, you'd only need 251 ft or for 3.800mhz, 264 ft (1005/MHz).

One thing that can be done is to use insulated wire. This has a lower velocity factor than uninsulated wire so a shorter length is required. While it won't be nearly enough to compensate, it should knock off around 10 ft of length, give or take a few feet. Our loop is about 250 ft of insulated wire and it is about 15 ft off the ground. It's a great NVIS antenna giving us rather solid coverage around the state (TX) and a bit beyond with much lower noise than our g5rv inverted Vee at 40 ft. It also does nicely on 40m. The antenna is fed at the corner with a 1:1 current balun.

Ideally, you want to maximize the area of the loop. I've seen some make a star pattern to increase the length of wire in a smaller area. You probably don't want to run the wires close together lest it form a twinline.

Alternatively, you might just cut it a bit short and match with the tuner. Feeding with ladderline would probably help any swr losses. Lower height loop antennas though seem to have lower impedances.

best regards,
charles

From: Jeffrey Embry
Topic: 1437 Message: 1437

...but here goes.

I live in an antenna restricted community and have a dipole for 40 - 10 meters in my attic along with a variety of Par Omni-angles for VHF/UHF. The dimentions of the attic is approximately 20 x 25ft. I would love to get on 80 meter CW. I can construct a wire loop and run it outside along the perimeter of the roof...basically laying on the shingles...or run it under the roof.

I am still not sure if this will load on 80...but will give it a go. Any thoughts or suggestions on this?

Hi,

The dimensions 20x25 will allow a horizontal loop about 80' in diameter which will load very well on 75/80M with a tuner. The alternatives are to either run a parallel feed line such as 300 ohm TV twin lead or 450 ohm ladder line down to a tuner at the operating position or to located a remote automatic tuner in the attic such as one of the SGC units and simply run RG58 to the operating position. Such an arrangement will work all bands 80-10 M with no difficulty. You will make tons of 80M cw contacts.

Do you know about the folded dipole? At first glance it looks like a loop, but it is completely squashed flat. Because the back-and-forth wires are close together, it behaves like a dipole (with an impedance transformation) rather than like a loop.

The point is, if you run your wires back-and-forth in close proximity, it may behave a lot differently than you'd expect. The doubled-back sections may behave like a single wire or stub. Keep them separated more.

I've seen articles showing full size loops (or dipoles) built in attics or other limited spaces, running the wire zig-zag to make it fit, but keeping all the wires apart from one another so none are in close proximity. (For example, draw a very fat "H", then trace its outline.) Yes it is a compromise but it works.

The other thing you can do, is make a 2-turn loop. In this case, where the wires go in the same rather than opposite directions, they can be close to one another, and you still get the benefits of a loop.

Regards,
Andy

I have looked all over the internet to see if a multi-turns loop would
work. I saw lots of them for receive but not for transmit. I have a 40m
Loop up. Can I run a second turn and use it on 80?. How far apart should it
be?.
I installed a piece of PVC tubing at each corner of my roof (flat roof).
They are 36" long. I could easily run another turn under the first one.

run RG58 to the operating position. Such an arrangement will work all
bands 80-10 M with no difficulty. You will make tons of 80M cw contacts.

Jim, VE3CI

Hi,
The dimensions 20x25 will allow a horizontal loop about 90' in circumference.

Thomas KN4LF Says:

Any closed loop with a length less than a full wave loop on the fundamental frequency will have allot of capacitive reactance and "may" radiate poorly, not take high power and create arcing in the antenna tuner. In my experiments with a full wave loop on 160 meters I started with the full wave of 558 feet and kept shrinking it down under a full wave until the above problems arose. I was able to shorten it from 558 feet to 418 feet.

From: charles allison
Topic: 1433 Message: 1447

Bob,

Having a loop at 15 ft or so seems to lower the input impedance to below 50 ohms, perhaps down to 15 or 20 ohms while a loop higher up will tend towards something like 100 ohms. 4:1 baluns are used to raise the impedance rather than lower them. Also, other bands tend to have yet different impedances. I used the 1:1 current balun because I had it more than any other reason. Some people use baluns and some use coax connected directly to the loop wire. If I were feeding a section of ladder line - I'd probably build one of Dr Ace's 4:1 baluns out of pvc pipe and old electrical wire but at present, I'm not using any ladder line on this loop. Come to think of it, I already built one of his baluns and it's on an 80m loop with about 30 ft of 450 ohm ladder line that we made up for field day. That loop itself uses electric fence wire (17ga bare aluminum) and after we finally fixed 2 runs of defective coax, it actually worked for field day but it was more like 25 to 35 ft up in the trees down at the county courthouse.

best regards,

Charles

Hi Thomas,

Well the question will be how do you get your 418 ft loop into the fellow's attic (20x25 ft) ?? He would like to make some contacts on 80M cw. I know he won't have any problem making contacts with a tuned loop 80 ft in dia. I have loaded such loops .... about 80' in 1, 2, and 3 turn loops with a simple balanced tuner and 100W. No arc, no smoke. Worked all bands. the single turn 80ft loop was the best.

I am not a fan of horizontal loops .... each to his own .... but I have used 80' loop vertically hung up in the trees .... works great 40-10M .... and not too bad on 75M. However putting it horizontal in the attic will no doubt limit its effectiveness.

By the way, I have experimented with 1/2 wave length loops and find that they are directional when oriented in the vertical position and fed in the middle of one vertical side. They are a neat antenna on 20M .... about 9' square. I hang them in the trees such that they can be rotated. I feed

them with parallel line to my trusty balanced tuner. If you scale that up to 80M you would have a loop 36' square. Pretty hard to get that up in the vertical position ....

KN4LF Says:
I forgot to mention that when I trimmed my 160 meter full wave loop from 558 to 418 feet the reason it worked was because the 110 feet of 450 window line acted as part of the antenna, as I still had close to a full wave electrically. But if you use a balun at a feedpoint the feedline will not radiate and you lose this advantage.

Jim yes it would obviously be impossible to get a 80 meter full wave loop in an attic without multiple turns, which would counteract the whole idea of the full wave loop which needs allot of open capture area. The small vertical transmit loop you mention works real well though.

KN4LF Said:
Any closed loop with a length less than a full wave loop on the fundamental frequency will have allot of capacitive reactance and "may" radiate poorly, not take high power and create arcing in the antenna tuner. In my experiments with a full wave loop on 160 meters I started with the full wave of 558 feet and kept shrinking it down under a full wave until the above problems arose. If that is true, you really ought to spell amateur correctly.

OK, for kicks I downloaded it.

Note: This is NOT the 1959 ARRL Radio Amateur's Handbook. Its title is "The Radio Handbook," 15th Edition, by well-known author Bill Orr. Looks like it is a lot of radio theory, but without an emphasis on amateur radio.

At 60 Megs, it is not for those with dial-up internet access.

Did not have a problem getting it to download. Perhaps the "not authorized" message one of you got is because of an internet setting on your computer, or cookies, or whatever.

Did not get any warnings about a virus either. I even gave it an extra scan to make sure, and the file seems to be OK. (Can virii hide in PDF files, anyway?) If it matters, my virus checker updated its database earlier this morning.

The book is copyrighted. Is the copyright still in effect?

Regards,
Andy

Hi to the group,

I would like to thank the person who made this download possible. The book has a lot of information that my students could use and I've now made it available to them as a download as well.

I've found that there are three types of people 1/. Those who lead. 2/. Those who follow. 3/. Those who complain about the first two.

It's been made available, it's free, so enjoy it and quite complaining and looking for something to bitch about.

Ve7agw, Al

1468. question

Yahoo group: SkyWires
Date: 2006-01-14 20:31:58 UTC
From: Jim Dunstan
Topic: 1468 Message: 1468

Hello group,

My question doesn't relate directly to a large wire loop. However my question may have general relevance to wire antennas. I want to get on 80M.

My present antenna system provides excellent performance on 40/20/15/10 Meters using a rotatable trapped dipole. My steel tower is located near to my operating position which is close to one end of my property. I have several tall trees at the other end (approx. 90 feet distance). I could string a shortened dipole between the trees and the steel tower and suspend a feed line in the middle. However I want to avoid this and would like to feed the antenna with coax feed line attached to the steel tower as is the cable feeding my present antenna. Given this situation one half of my dipole (65') would extend from the tower to the trees. The other half of the dipole is the question (I have no trees on the other side of my tower).

The other side of the dipole will be directed straight down forming a center fed inverted 'L' antenna. However, in order to do this and keep the end at least 6' above ground would require a tower approximately 70' high. My Tower is 48' high (22' short). I am not particularly interested in vertically oriented radiation of a vertical half of a half wave antenna .... and I will have to fold it in some way to compensate for the 22' shortfall. It occurred to me that I could construct this vertical half of my dipole (65') by folding it in half (32.5'). I could use open wire line 32.5' in length. One side of the open wire line would be connected to the center feed point of the dipole, the feed line would drop 32.5' at which point the feed line would be shorted and result in another 32.5' running parallel right back up to the feed point and left unconnected to anything. The antenna currents on the feed line would be equal and opposite in direction thus cancelling out radiation from this half of the dipole for the most part.

The result would be: A horizontal 1/4 wave wire (65') at 45' which would radiate as one side of a normal 1/2 wave dipole. The other half of the dipole would consist of 32.5' of balanced line that would hang in a vertical orientation (about 1' from the tower) and represent an electrical 1/4 wavelength but basically cancel out radiation. The feed point would remain close the 50 ohm impedance ... easily fed with standard coax. with reasonable SWR.

Will it work? .... eg reasonable feed point impedance, vertical component cancelled out, and dipole reasonably balanced, and shortened half using the stub arrangement. Comments?

Thanks

Jim, VE3CI

1469. 4.1 or 1.1 the real answer?

Yahoo group: SkyWires

Hello....
I have had this big loop up for about 3 years and have really liked it but as I read all the information and keep changing it.. Here is the setup. 530 feet 14g wire up about 50 feet, fed with 60 feet of 450 ohm ladder line right into the shack into the tuner. Now the tuner has a 1.1 curent balun, and it gets very warm/hot with 1kw out on 1.850 the tuner is T network mfj989D (the new one) with the 2-500pf caps. I have tryed a dx engineering 1.1 10kw balun hooked right to the tuner and have the same warm/hot results. The inductor seems to stay cool. The SWR is 1.1 down at about 1.720 but up at 1.850 is very high. I have also tryed a direct feed, right to the s239 on the back of the tuner, one side to the center and the other side to ground, No balun. This way of course there is no heat(no balun)....Is the wire just to long? Would a 4.1 balun be better that the 1.1? I hear guys running this way all the time but never hear about the hot balun. I have also installed a 100pf doorknob on the output cap and it just allowed for a little lower inductor setting.
Thanks for any input......
Larry

Hi

Since a loop antenna is really a balanced device with in your case a
balanced feedline the best tuner in this case would be a balanced
feedline tuner.
MFJ now has a balanced tuner and maybe you should look into that.
The old Johnson matchbox is a balanced feedline tuner but does not
cover 160 meters.

Hello Larry,

Your 1:1 current balun is heating because it is trying to isolate a high impedance load from ground. For a current balun to be effective its common mode impedance should be at least 10 times than the impedance it is trying to isolate. Even though you might have a 4:1 balun between the ladderline and the current balun the "cold" side of the 4:1 balun is still at 225 ohms above ground (assuming a non-reactive 450 ohm load at the antenna feed point) and this high impedance is still presented to your current balun. If you have a lower impedance such as 100 ohms at the antenna feed point and a reactive component the ladderline will "transform" that combination into a new higher resistance and reactance component that both the 4:1 balun and the 1:1 current balun will have to deal with. Considering such baluns are usually designed to be fed from 50 ohm and to 200 ohms for the 4:1 and to 50 ohms for the 1:1 both types of baluns basically lose their predicted electrical performance and can become very lossy in the process. Richard Measures and W4RNL in his cebik.com website give very good analysis of these conditions.

The only solutions that seem viable are either link coupled tuners such as the old Johnson matchboxes (80-10M) or the ganged dual roller inductor balanced L tuners that also present a true balanced feed to the feed system.

I've been experimenting with a 40M and a 160M loop for the past few years both fed with 450 ohm ladderline and presently have a pair of Johnson KW matchboxes for 80-10M and am using for 160M a Murch UT-2000B with factory triple core balun (in a standard T configuration I put it into - strapped both input capacitor halves together). The Murch is the only commercially made "tuner" that has achieved perfect feed balance for me on 160M.

I am building a 160M link coupler with Johnson AM broadcast band 5KW link coupler components into an old Johnson KW Matchbox. I am using a loaded Q of about 5. I've tested the 160m link coupler configuation on the bench at 1500W PEP into the 500 ft. loop and it performed nicely on 160M, flat match at 1900KC, and without touching the tuning controls, lower than 1.8:1 VSWR at the band edges and absolutely no measureable component heating, and perfect output balance across the band.

One thing I have noticed with obtaining perfect balance on the feed that I can hear foreign DX consitantly on 160 and 80M because of tyhe greatly reduced manmade and lightning nois pickup on the feedline. When I call them they usually respond. You have to hear 'em to

work 'em.

Best to you with your project.

1474. Loop Advice

Yahoo group: SkyWires
Date: 2006-01-21 00:06:28 UTC
From: Scott Gordon
Topic: 1474 Message: 1474

I have had a 75 meter loop up and down for several years. I guess I try a different antenna every once and a while and always end up putting my loop back up since reports are always the best. I feed it with 450 ohm line and use it on all bands. I even had good results shorting the ends together and using it on 160 meters.

Now my question, I would like to get up a loop on 160 meters. But my measurements I am only going to be around 450 and maybe can get it to near 500 feet which is probably 50 to 100 feet or so short. I will be using 450 ohm line. Does anyone know of what kind of results I might see with this length of loop? Should I just stick with my 75 meter or will I see any gains going bigger?

From: nc9k
Topic: 1474 Message: 1475

Hello Scott,

I've been experimenting with a 450 ohm ladderline fed 40M loop on 80M with fine results. The ladderline is 75 ft. long. The loop itself is only a halfwave in length and presents something like 10 ohms feedpoint resistance with a high capacuitive reactance. The feedline length of about 1/4 wave on 80M transforms the 10 ohms to a much higher resistance that my Johnson KW Matchbox has no trouble with even at 1500 watts input.

With 450 ft. instead of 530 ft. on 160M your loop feed resistance will be about 30% lower than the theoretical 100 ohms and you will have a sizable capacitive reactance component at the antenna to feedline junction. The length of your feedline in wavelengths will determine the resistive and reactive components ultimately presented in your shack. You will have excellent results on 160M when you loadup into the setup. On 80M you will have almost 2 wavelengths up which put you at about a 45 degree angle of maximum radiation. You will be able to work excellent DX.

You can get up 530 ft of wire up if you fold part of the length in the form of a V. This V can come close to the shack and then connect the rest of the way into the shack via 450 ohm ladderline. This setup will get you close to 100 ohms feed impedance with low reactance at the antenna to feedline junction.

73's and good DX,

Leland NC9K

Leland,

Thanks for the information. I hope to get this up over the weekend.
I am not sure I understand when you say pull it back in a V?

----- ----
- -
- -
-
450 Line

Can't draw it here very well but are you saying where you pull the V back to connect the feedline there? I have about 75 foot of 450 ohm ladder line I will be using. My 75 meter antenna was in a Traiangle, this one will be the same but on larger.

Thanks,, Will let you know how it does.

Subject: [SkyWires] Re: Loop Advice

Hello Scott,

I've been experimenting with a 450 ohm ladderline fed 40M loop on 80M with fine results. The ladderline is 75 ft. long. The loop itself is only a halfwave in length and presents something like 10 ohms feedpoint resistance with a high capacuitive reactance. The feedline length of about 1/4 wave on 80M transforms the 10 ohms to a much higher resistance that my Johnson KW Matchbox has no trouble with even at 1500 watts input.

With 450 ft. instead of 530 ft. on 160M your loop feed resistance will be about 30% lower than the theoretical 100 ohms and you will have a sizable capacitive reactance component at the antenna to feedline junction. The length of your feedline in wavelengths will determine the resistive and reactive components ultimately presented in your shack. You will have excellent results on 160M when you loadup into the setup. On 80M you will have almost 2 wavelengths up which put you at about a 45 degree angle of maximum radiation. You

will be able to work excellent DX.

You can get up 530 ft of wire up if you fold part of the length in the form of a V. This V can come close to the shack and then connect the rest of the way into the shack via 450 ohm ladderline. This setup will get you close to 100 ohms feed impedance with low reactance at the antenna to feedline junction.

73's and good DX,

Leland NC9K

Hello Scott,

Say you can put up a loop of 450 ft. circumference; this is a bit short for 160M. Make the loop 430 ft long and fill in the remaining 20 feet with nylon rope. Then attach 50 ft lengths of wire to the ends of the 430 ft. of wire and attach the opposite ends of the 50 ft wires to 450 ohm ladderline. (Be sure to use appropriate strain relief where needed to prevent wire breakage.) This will lengthen the antenna system to 530 ft. without too much pattern distortion. This is what I meant by pulling it back in a V.

Hi,

Perhaps the link supports advertising for 'NNB' or NNB has put a little latent program on your machine that periodically redirects your browser to their site, or simply pops up on your machine periodically, or something supernatural is happening hi hi.

Nick,

Thanks for the help, I did get my loop up but will need to lengthen it. I calculate that right now I may be 90 feet short. It has a 3:1 match up around 2.3 mhz from what I can see on my old mfg swr analyzer.

I hooked this up to my tuner via 450 ohm ladder line run directly to the tuner. I was very discouraged witht the results. It was extremely noisy, much to the fact of greater then my vertical or windom. I had a 4:1 balun spare on the shelf so I hook it up and attached to the tuner coax connector and much to my belief the noise was gone and I worked several west coast stations on 40 meters with 100 watts with 59 reports. Signal was 1 to 2 S units better on receive the windom or vertical. I have made a couple contacts on 75 as well. I have not tried it out on 160m.

So I am not sure why my tuner would not work when connected directly with 450 ladder line? This is a old Dentron Clipperton-T antenna tuner. I do have a old MFJ on the shelf that I will try this with as well.

I know I can get about 30 more feet on the loop which will give me about 466 feet. The question that I have taken so long to ask you, if I cut the loop and add the rope then attach if I add in the wire 40 feet on each Vee can I do this anywhere in the loop or only at the feedpoint? I am not sure I can do this at the feedpoint area.

1483. Loop Advice

Yahoo group: SkyWires
Date: 2006-01-24 16:36:45 UTC
From: ve7agw
Topic: 1474 Message: 1483

Hi Scott and the group,

You can add more wire to the length of a loop at any point in the loop as long as you make your connection mechanically and electrically sound and protect the joint. That is unless you are using bare wire then you don't have to protect the jointing points.
The loop is just what it says a "loop" so adding to the circumference can be done at any point.

Hope this helps,
73...de ve7agw
Al

Nick,

Thanks for the help, I did get my loop up but will need to lengthen it. I calculate that right now I may be 90 feet short. It has a 3:1 match up around 2.3 mhz from what I can see on my old mfg swr analyzer.

I hooked this up to my tuner via 450 ohm ladder line run directly to the tuner. I was very discouraged witht the results. Scott,

Go ahead and add symetrically spaced similar-sized multiple V's if
you can to reach 530 ft. The pattern won't be perfect but at least
you will come much closer to 160M resonance.

Many commercial tuners are very unbalanced on the "balanced" line
output. The unbalanced output condition of your Dentron tuner caused
the ladderline to directly pick up electrical noise. The external
balun you connected is electrically more balanced than the one you
bypassed in the Dentron. You have to run a true balanced 450 ohm
line to reap the low noise benefits of the loop antenna.

Outside of the Johnson Matchbox series link coupled tuners (perfect
output balance) the only commercial tuner I have found with very good
balanced output (at least on 160 and 80M)is the Murch UT-2000B with
factory triple core balun. I detected almost no inductor or balun
heating with 1500W running through it for 5 minutes on 160M. I am
still making my own link coupled tuner for 160M when I get the time
to put the components into their chassis. This will give me perfect
line balance on 160M. For now the Murch will do.

Scott,

Go ahead and add symetrically spaced similar-sized multiple V's if you can to reach 530 ft. The pattern won't be perfect but at least you will come much closer to 160M resonance.

Many commercial tuners are very unbalanced on the "balanced" line output. The unbalanced output condition of your Dentron tuner caused the ladderline to directly pick up electrical noise. The external balun you connected is electrically more balanced than the one you bypassed in the Dentron. You have to run a true balanced 450 ohm line to reap the low noise benefits of the loop antenna.

Outside of the Johnson Matchbox series link coupled tuners (perfect output balance) the only commercial tuner I have found with very good balanced output (at least on 160 and 80M)is the Murch UT-2000B with factory triple core balun. I detected almost no inductor or balun heating with 1500W running through it for 5 minutes on 160M. I am still making my own link coupled tuner for 160M when I get the time to put the components into their chassis. This will give me perfect line balance on 160M. For now the Murch will do.

1486. Skywire loop for 11m

Yahoo group: SkyWires
Date: 2006-01-30 21:21:06 UTC
From: Robert
Topic: 1486 Message: 1486

Would this work on 11m?

should I make it a 5/8 wl?

How high should I put it?
thx

1487. Re: [SkyWires] Skywire loop for 11m

From: Dr.Ace Ratliff
Topic: 1486 Message: 1487

Robert,

Make the loop about 37 ' 2 1/2 " .

On the higher frequency bands (11 mtrs) a full wave loop antenna can be oriented as a vertical diamond or vertical cube. Fed at the top or bottom corner of a diamond this antenna has horizontal polarization, so you would probably want to feed a side corner for local (Vertical Polarized) communications.

Let me clearly state this Fact.
"A vertically oriented horizontally polarized one wavelength loop antenna with the bottom of the loop 1/2 wave length above ground is a FINE antenna".

Do NOT put the bottom of the vertically oriented loop more than 1/2 wave length above ground i.e. 18 1/2 ' .

I just purchased a Alpha Delta swl-dx antenna and
was wondering if anyone else has ever used it and what
you thought of it and also I noticed it mention Ham
bands on the advertisement and has anyone ever used it
on the Ham.

Hi Larry

Isnt it a bit late to ask for opinions now that you have bought it.?
How are you going to feel when everyone flames you saying ITS JUNK !?

hehe.....

Now about the antenna..

It seems a nice enough sloper.
Its cut lengths and the traps were not selected for ham band use , but
if you realy wanted to try and TX on it ide sugest using low power
only and a good tuner.

I believe the manufacturer specifically says it
is NOT meant for transmitting. It is designed as
a receive only product.

That said, good luck with it as a transmitter.

Hiya

If you noticed , I did not recomend it for transmitting and even went
far enough to say it wasnt made for it.
From a technical standpoint though you COULD transmit with it.
As I said , with a good tuner and on low power it could be made to
radiate.
With a good tuner you can turn a wire fence or a house downpipe into a
radiator., (and even a toy slinky)

I didnt say it would work well.

In fact , with the wrong traps installed and wrong cut lengths it
would work about as good as the dreaded slinky.

regards

Rhombic antennas can make pretty good, high gain antennas. Problem is ... you need a lot of real estate, and they tend to be fairly directional.

1500. Connecting to 450 ohm ladderline?

Yahoo group: SkyWires
Date: 2006-02-11 04:02:00 UTC
From: JD WG5B
Topic: 1500 Message: 1500

What is the best way to connect 450 ohm ladder line to the antenna wire?
some type of commercial strain relief? I was just curious of any
suggestions, as I just soldered mine direct, but it is pulling the
ladder line apart at the connection...

ARS-WG5B

1501. Re: [SkyWires] Connecting to 450 ohm ladderline?

Yahoo group: SkyWires
Date: 2006-02-11 05:16:08 UTC
From: Steve Book
Topic: 1500 Message: 1501

I cut a T out of 1/4" plexiglass, drilled a 1/4" hole
in each of the top parts of the T and soldered C10-14
ring terminals on the ends of the loop antenna wire
and the ladder line. I used 1/4"- 20 brass screws and
nuts to make the connections through the holes in the
plexiglass and taped the ladderline to the down
portion of the T. It has been through some pretty
strong winds this winter in eastern Ohio and it's
still holding fine.

JD,
Here's an easy method .
Where the 2 antenna ends meet at the feedpoint use a strain insulator like
http://www.fairradio.com/0ins-egg.jpg

or a similar strain insulator .

Then connect each side of the 450 ohm ladder line to each side of the strain insulator .
No more pulling apart .

Hi,

The answer is simple .... use a standard strain insulator to complete the loop. then simply solder the 450 ohm line across the insulator .... voila.

If you want to see a drawing that might be useful, check
http://ne.mara.net/graphics/feedpoint.jpg

I use it on my loop. The #14 wire goes through the holes at the top, then loops back and is ty-wrapped, and then loops down to the twinlead connections. I used solder terminals on both the loop wire and the twinlead ends. The twinlead is also ty-wrapped to the piece of plastic to prevent flex damage.

Topic: 1500 Message: 1506

JD and the Group,

I used a 1/2 PVC pipe Tee and drilled two holes for 1/4 inch Stainless Steel bolts to go threw on each side of the top part of the Tee. Looped the antenna wire around the bolt on the inside and tied a knot then solder the end to the Ladder line that comes up threw the vertical part of the Tee after you drill a hole threw it to put a tie strap threw the hole. Then loop the ladder line up and over the plastic tie effectively making a strain relief for the ladder line.
I've used this method now for years and they out live most of the commercial strain relief units. I think this one was originally listed in the ARRL Antenna Book, not sure which addition though.

I went to Wal Mart, purchased a polyethylene cutting board , 3/4" thick,
big enough to make about 8 strain relief insulators.
You can cut it with a hacksaw, however I used a Dremel to cut out a tee
I layed out in pencil, then used it to drill each arm to accept each leg
of the loop, I cut a 1/2 " square in each to solder the legs to the LL,
which is brought up to the cutouts through to more holes on either side
of the trunk of the tee.

Hope this helps It works for me. Good luck.

I am upgrading my antenna farm after much of it damaged by Hurricane Wilma last year. I am considering a 171 meter loop for a starter. I have a 35 ft tower and plenty of room especially to the west of the tower is open pasture. I was considering a Delta or diamond driven at the top of the tower and sloping downward. The plan is to place the tallest posts that I can find locally in the pasture. I expect 15-20 ft will be maximum that I can set up alone. Anyone have opinions on best way to drive this? coax is available to the tower through underground conduit. Ladderline could be run from outside of shack or base of tower . BTW this will not be used with high power. mostly 20W psk31 and 100W SSB voice. Thanks for inputs. Dave, KR4YD, LaBelle, Florida. <sk>

Dave,

I have a similar type of arrangement except the area is not as open as you have. I used some large Red Cedar trees on my property to erect a Delta Loop for 80 meters then changed it to a square shaped loop up about 70 feet at the highest slopping to about 30 feet at the lowest corner.
I feed it with 300 ohm ladder line down to a remote 4:1 balun just outside the shack. Thus keeping the line losses to a minimum. Ladder line will virtually give you no line loss and the balun will stop any rf from coming back into the shack on the ground side, also matches gives you a better impedance match from coax to ladder line.
I originally had feed it with straight coax but had too much line loss and too high of a miss match on the impedance. With the remote balun the AT-180 tuner will tune it with no problems and gives a very wide band width. I only use 100 watts at the best of times but I have feed it with full legal limit with no problems.

Hope this gives you some insight into the loop and have fun experiementing.

Dave,
I'm a fan of using either ladder line, window line, or even cheap-o 300 ohm twin lead - in my opinion (uninformed by mathematics, only by experience ;-) the coax is the least attractive of the lot.

I've been having a great time running low power into my 40m loop (which is only about 18 feet high at the highest point and driven with twin lead)... for a few watts of output, the antenna gets all over the place. I don't run more than about 100 watts ever. If you're packin' some serious heat, you might run away from the twin lead and go with real ladder line - but then you're back into the realm of mathematics in trying to figure out what will work best.

DOn't get me wrong - I love math... I just do enough of it at work to not want to worry about it at home ;-)

- - - REPLY: [I am not familiar with the PAL connector, but your
description makes it sound same as a type M (or PL-259) which is for
terminating an UNbalanced line (such as coaxial cable).
Examples of balanced lines are TV twin-lead, and ladder line, where
both conductors are equal in that they are unshielded and run
side-by-side.
Typically, UNbalanced coax lines have impedences between 52 and 93
ohms, whereas balanced lines typically run at 300, 450, or 600 ohms.
You can convert one to the other, at the termination point, by use
of a BALUN. It matches a BALanced to an UNbalanced line, of the same
impedence (if 1:1 ratio) or of different impedences (if, say, 2:1 or
4:1 ratio)].

From: JHR
Topic: 1517 Message: 1518

I respectfully question some of the advice PM has given.

My point of departure is the discussion of balanced vs. unbalanced feed lines IN THIS CONTEXT, and with the nature of the PAL connector mentioned in the original question post.

1) You say you have an Eavesdropper antenna (I have one, myself) which uses a BALANCED feed line. Sometimes it comes with a balanced 50 ohm feed line (newer iterations of this antenna come with a lightening/static arrestor - whereas my older model does not.) You can ground that to a copper-clad iron stake in the ground (preferably using the shortest cable to ground you can devise.)

Other iterations of this antenna come with a coax cable lead in wire, which (I believe) is also "balanced" as it is a dipole -- balanced in that the internal conductor on the coax is the "hot" side and the outer cable braid conductor is the "ground" or "counterpoise" of the antenna -- which is what is grounded.

This antenna is designed to be attached (regardless of which feed line is supplied with your model) to the 50 ohm connector on the radio.

2) A PAL connector is a coaxial connector, but it is NOT THE SAME AS A PL-259 connector. They use these in Europe whereas we more commonly use an F-connector. Grundig/Eton radios often use these as the radios are marketed primarily for European sales, where in Europe it is a very popular brand name, and secondarily in the US - even though we are a very large market for them.

3) I would connect the hot side of your Eavesdropper to the tip of my 1/8 inch phone plug and the other-ground- side of the Eavesdropper to the ring/shaft of my phone plug antenna connector --- or hot to center pin, and ground to outer ring of my PAL connector if using that one. NO RF EARTH GROUND is needed, but I would disconnect it when not in use. No other ground (i.e., RF Ground) is required, as the chassis of the radio is connected to the ground (ring) on the antenna connector.

4) I agree that the electrical system ground (third prong on power cord) is a POOR RF GROUND and is not suitable for that purpose.

Just my take. Your mileage or opinion may differ, of course.

REPLY:
To clarify, let me say first that I've never heard of a balanced
feedline with an impedence as low as 50-ohms, and would suspect that
it's UNbalanced. If it is shielded (that is, with a center conductor
surrounded by an outer shield - whether braid, foil or whatever kind
-, that describes a "coaxial" cable and is UNbalanced.
As for connectors - whether Type F, Type M (PL259), phone plug
(PL55, PJ068, or the smaller size versions), or PAL - all these with a
center pin and an outer ring/sleeve/skirt/whatever are UNbalanced
termination connectors.
If it's two equal and parallel conductor lines, or two equal
side-by-side connection screws/posts on a terminal board, all these
are BALanced lines and terminations, typically 150-ohms minimum.
The Eavesdropper and any other dipole or doublet antenna is by

design a BALanced antenna. As such, it does not require either a DC or an RF ground. The entire antenna is self-contained and complete, as is, and does not rely on a ground.
The antenna's feedpoint impedence is about 50-ohms, making it suitable for feeding with 50-75-ohm coaxial cable. While a 1:1 balun may be installed at the feedpoint, to match the "BAL" to the "UN," it is not necessary.
Similarly, at the receiver, while such a mismatch may again exist, a balun is not necessary.
Regardless of all other considerations, a DC ground is always a GOOD idea. An RF ground, in this case, would serve no purpose.

Hi Leland,
After reading your comments about the Murch UT-2000B Transmatch I searched eBay until I found a nice one. It took a long time, lots of UT-2000A tuners, few 2000B.(For those who don't know the 2000A doesn't cover 160 mtrs). My Transmatch has been modified in accordance with research done by Doug DeMaw to make it more effective in harmonic rejection. Complete documentation of the changes are in an August 1981 QST pages 42-43 article.
I just got it Friday and have it hooked up and tested. It seems to be a very nice tuner.

Subject: [SkyWires] Re: Loop Advice

Scott,

Go ahead and add symetrically spaced similar-sized multiple V's if
you can to reach 530 ft. The pattern won't be perfect but at least
you will come much closer to 160M resonance.

Many commercial tuners are very unbalanced on the "balanced" line
output. The unbalanced output condition of your Dentron tuner caused
the ladderline to directly pick up electrical noise. The external
balun you connected is electrically more balanced than the one you
bypassed in the Dentron. You have to run a true balanced 450 ohm
line to reap the low noise benefits of the loop antenna.

Outside of the Johnson Matchbox series link coupled tuners (perfect
output balance) the only commercial tuner I have found with very good
balanced output (at least on 160 and 80M)is the Murch UT-2000B with
factory triple core balun. I detected almost no inductor or balun
heating with 1500W running through it for 5 minutes on 160M. I am
still making my own link coupled tuner for 160M when I get the time
to put the components into their chassis. This will give me perfect
line balance on 160M. For now the Murch will do.

Are you using an old tube radio? What transistor base rig has such poor
built-in harmonic rejection this becomes a concern?

Hi Erik,
It was not a concern for me. The transmatch was modified before I acquired it. I put the information on the post for the benefit of other people. Many people still run tube type radios. The only tube type equipment I currently use are 2 HF amplifiers.

I agree with Erik. The primary function of a coax in/out transmatch is to convert the impedance of the coax feed line to a resistive 50 ohms. Once this is accomplished harmonic rejection is looked after by the output filter contained within the transceiver. With modern transceivers 2nd harmonic attenuation is not a consideration, providing a proper load is.

Hello Dr. Ace,

I'm glad you like the UT-2000B. I strapped both halves of the input capacitor together in mine thus putting the tuner into a conventional "T" configuration. This provides for potentially greater efficiency when feeding low impedance loads. The "Ultimate" T configuration that these tuners originally came as has lost favor for harmonic attenuation. I always use a high power low-pass filter after my old PI network output tube amplifiers and that seems to be sufficient to keep my harmonic radiation very low. But someone running a broadband solid state amp that does not have output low pass filters like the PI's in mine would have to be concerned about additional harmonic attenuation...

I will be pulling my 160M 2KW+ capacity (Johnson 5KW AM broadcast components found on ebay) link coupled tuner project together soon. I have everything needed but the actual style of knobs I want to use. I will take photos and post the results as a file in this discussion group once I finish it. I have already temporarily assembled the components on my bench and after setting the coupler for a flat match on 1900 Kc the VSWR at either band end remained under 1.8:1 without further adjusting the tuner. This test was conducted into 50 ft. of 450 ohm ladder feeding my 35 ft. high 500 ft. loop.

I also recently modified my Miller AT-2500 auto-tuner to operate on 160M and also added a 1:1 unbalanced to balanced output inside it. I am presently running this 160-10M into my 500 ft. loop. I am leaving a Johnson KW Matchbox parked on my 135 ft. loop thus allowing me to switch back and forth between the 2 loops on the higher HF bands.

In the summertime I like the extra DC isolation that only a link-coupled tuner can provide during thunderstorm season and will be running link coupled tuners 160-10M during thunderstorm season. I know nothing will stop a direct strike but a link coupled tuner sure adds extra protection from induced voltages caused by nearby strikes. I also run 1/8 inch sparkgaps and bleeder resistors outside the house on the ladderline feeds. So far so good...

1526. Re: [SkyWires] Re: Clarifying Ant Lines & Grounds

Yahoo group: SkyWires
Date: 2006-02-28 04:53:58 UTC
From: JHR
Topic: 1517 Message: 1526

PM -- I think we agree about what constitutes a balanced versus unbalanced feedline. I also think we agree the Eavesdropper antenna is a balanced dipole design. I can confirm, by both research and ownership, that the Eavesdropper is a balanced dipole design, with a 50 ohm balanced feedline - that is what is specified in the specifications. The feedline is a 50 ohm parallel conductor cable (looks like a small gauge zip cord/lamp cord).

I think my only disagreement lies in the concept that certain types of connector plugs are, somehow, inherently balanced or unbalanced, or are only used for a single type of antenna. I believe the connector is neutral as to whether or not the overall antenna or feedline in his balanced or unbalanced - the feedline/antenna design decides the matter, regardless of how you connect it to the radio. You can use the same kind of plug on either balanced or unbalanced lines. How do I know? I have used each type of plug for both balanced and unbalanced antennas, depending on my whim, and the radio intended to be attached to it.

Thank you for your considered, and carefully crafted informative response. Happy trails to you.

Best Regards. /////////// Richards ////////////

Like Dave said, "yes and no! using a coaxial type connector on a
balanced line will add a different capacitance/inductance at the
connector, but it will be so minor (as) to be of no practical concern.
Dave KR4Y."
Ideally, a perfectly balanced system will treat each side of the
line equally. The coaxial type connector typically grounds the outer
conductor. Well into the 70s, most general coverage receivers were
factory-equipped with a three-screw antenna connector strip, the third
screw being grounded and having a jumper strap for also grounding the
second screw, or not, according to whether you wanted to feed the
receiver with a balanced (as per doublet/dipole) or unbalanced (as per
longwire, vertical etc) antenna.
From what you say, I gather the Eavesdropper maker has apparently
eliminated the need for a balun by coming up with a balanced feedline
that is the ideal impedence for the dipole antenna. Brilliant. If it
is not too lossy, they should offer that feedline seperately, in
various lengths.
Of course, matching cheap and readily available 300-ohm TV twin-lead
to cheap and readily available 75-ohm RG-6 coax by means of a $2 TV
line transformer (balun) is not impractical at all. A drawing of this
hook-up appears on my site, SWLcs.KC5JK.com, on the "Antenna Farm"
page, under "Windom Antenna." And those TV baluns will even handle up
to about 35-watts of RF too, at HF, before they explode.

Well Paul , good news if you wish to call it that. The lamp cord that is commonly called zip cord is pretty near what you ask for. Most of it is near 72-75ohm impedence depending on spacing and size of conductors and if the insulation is magnetically netural the parallel conductors are nearly always correct. of course things will vary with manufacturer. Anyway if you have a good length of it terminate the far end wth a 75ohm carbon resistor and sweep it with an antenna analyzer. I thing you will find it pretty flat through the HF spectrum. Dave

Hi Dave,

You are correct. Zip cord is about the only low impedance balanced line commonly available these days. In the northern communities the Native Trappers Associations supply their members with commercially made 3-5Watt battery (dry cell) commercial SSB transceivers. When these transceivers first came out many years ago they were designed for low impedance (75 ohm) balanced output. The antennas the trappers carried with them were dipoles equipped with thin 75 ohm balanced feed line that was brown in color and about the size of thin telephone cable. I believe Belden Cable manufactured it ... as well as a more robust 1 KW version. Many years ago I used the 1 KW version balanced line to feed a loop (cubicle quad). It was a wonderful antenna and worked DXCC with it.

As far as I know the cable companies no longer manufacture 75 ohm balanced RF cable. Trappers in the North who still use the old radios now use ordinary zip cord from the hardware store for feed line with satisfactory performance. Now there are all kinds of zip cords and speaker cables that are suitable. It would be nice to have some kind of formal assessment of the various products from an RF point of view.

EG .... line impedance, attenuation/100 ft, and power handling capabilities. Right now it is try whatever looks good. I now operate QRP most of the time and my latest project is to use some standard #16 copper speaker wire twin lead. I'll be doing some testing to see how well it works ..... it certainly is nice to work with.

Jim

Yahoo group: SkyWires
Date: 2006-03-09 22:39:56 UTC
From: charles allison
Topic: 1535 Message: 1535

Hi,

What I've done is to cut a 1/4" thick piece of lexan to about 1x3" and then drill 3 holes - 1/4" clear. I then put in 1/4-20 bolts in the outer two with washers, lock washers and wingnuts. Voila', instant connection for wire to 450ohm ladder line complete with a hole for support. the plastic is easily drilled with a small electric or hand drill and easily cut with about any sort of a saw. A piece that size is probably scrap and might could be found at the hardware store or at the local glass company.

best regards,

Charles

Hello Listers,

My name is Ben Ramler, K0BLR. I just joined the list as I just bought a FT-100. I'm only a tech right now and my main interest is VHF/UHF. I have no Tower. I'm doing this in preperation for when I move into a house. I live only in an apartment right. Does anyone on the list know if there are wires for 6 meters and two meters?

thanks,

Ben Ramler, K0BLR
Granite Falls, MN

Absolutely - there are a bunch of wire antennas you can make for 6 and 2M - quads come to mind as a good gain antenna. Nice and small too. A wire dipole works too when the band is open - and they are also small. You can make a simple vertical loop for 6M that is only 5 feet on the side, and use PVC for the spreaders - simple and it works

Jeez, I would think so! While I must admit to not being an EE or otherwise qualified to specify a safe distance from such a high voltage line, I would have to think the 60Hz noise you would likely pick up would make this idea prohibitive in the second place!

But in the first place and this is hypothetical: If you wanted to "steal" the juice from an overhead line by inductively coupling to it (this is clearly illegal anyhow), how much closer, short of climbing the pole, would you ever want to get?? There's a reason why the higher voltage transmission lines are higher on the poles and further away from you.

I think yours is a damn foolish idea. Didn't those shocks learn you anything?

Any ungrounded wire will develop a induced static charge. You can measure a static charge is on any ungrounded antenna.

In power and telephone line construction un-terminated suspension cables and lines are routinely grounded during construction to prevent the buildup of a lethal static induced charge.

The charge is typically higher in areas with lower humidity and high winds.

The source of the induced charge can be adjacent power lines, lightning, rain, snow, or wind.

I've had a one hundred foot end fed wire develop enough static in a snow storm to cause an arc across a PL-259 connector approximately every 10 seconds.

I keep the loop disconnected from any equipment and terminated with a 300 ohm (just something I had on hand!) resistor when I'm not on the air.

Hi,

If the voltage can be discharged to ground then slowly builds up again then it is likely that it is a result of static charge. If the voltage is AC, and can produce some level of consistent current flow then it is indeed caused by induction from some source of alternating magnetic field. My guess, given your description of the antenna location, is that the voltage is simply the result of a build up of a static charge. The usual sources of static charge are moving particles in the air.

I think I've mislead you! I don't ground the antenna when not in use. The feed line comes through the rear wall of the shack on two parallel threaded rods (each in its own pvc pipe). I attach the resistor across the rods when I'm not using the antenna. There is no attachment to ground. My theory is, if it's floating, it's neutral and won't attract the lightning. Whether that's true or not, it has worked for me.

I've only noticed the snow static that one time. Probably then because the antenna was unterminated/ungrounded. Since then, I've either shorted the antenna (as with the resistor) or connected it to ground through an rf choke/high value resistor.

Perhaps, because of the "nothing bad has happened so it's not going to" syndrome, I've become complacent. I've operated in snow storms since and nothing has happened to the rigs, likely because there has been a DC path (somewhere!) bleeding off the static charge.

It wouldn't hurt to add an rf choke (or a high value resistor) from the hot side of the coax (before the tuner assuming balanced feed line) to ground to keep the static under control.

Hi All,
End fed wire and/or loop antennas can develop very high static voltages on them.
This static voltage can easily be high enough to knock the front end out of sensitive receivers.
To overcome this problem, I suggest you connect a resistor from the coax center to shield (if you use coax) where the antenna wire connects to the coax or across a parallel feedline.
Only use a non-inductive resistor, carbon resistors work fine.
Don't use wire wound or metal film resistors.
The resistance value is not critical. The resistor can be left in the circuit at all times and will have no measurable effect on VSWR , power loss , etc.
I suggest about a 56K ohm 1/2 watt resistor for receive only or if transmitting with up to 100 watts.
If you will be transmitting with high power "QRO", I suggest using about a 1 Meg ohm 1/2 watt resistor.

Topic: 1551 Message: 1551

Dr.Ratliff, do bare wire dipoles acquire similar charges? My 28 month old FT-857 suffered a recent partial deafness and loss of S meter display. Took 2 weeks and $135 (including shipping both ways) for Vertex Standard to put it back in like new condition. Its "illness" began on a windy day while I was using the single feedline crossed 40/80 meter dipoles out at my shop/shack building. Would your "static bleeder" work for dipoles too? I think I'll stick with the house antenna (vertical 5BTV) until I hear your reply on this matter. Hmmm, do verticals avoid static accumulation or should they have a "bleeder" connection also? I'm afraid I'm acquiring a rampant case of ASAP (Antenna Static Accumulation Paranoia)(G) Well, completely sane or not, my questions are serious ones. For, to those of us living anywhere on the great plains, a day without noticeable wind is a rare event.

That's the first thing that came to mind with me too. But if it is truly a continuous loop, and doesn't have something like a capacitor in the middle of it, then it shouldn't maintain a static (DC) charge.

If it is a continuous loop, then presumably this 300 volts (if real) must be an AC measurement. Perhaps its size makes it very good at reception and the induced voltage (probably measured with a rather high impedance load) is what it picks up. Magnetic induction normally causes a current in the secondary loop, and if you don't have a short or low impedance load on it, the voltage can be somewhat large (depending on self inductance, which probably is quite large in his case).

Does he live in a house with no AC power? Otherwise, there's got to be power lines nearby (to act as a transformer primary), just not of the very high voltage kind.

Regards,
Andy

>KD5SAK

Hi Harold,

All antennas may accumulate a static charge .... the amount of charge will be related to the amount of wire up there. Whether the charge remains on the antenna depends on the design of the antenna .... eg whether the design includes a Direct Current path to ground. Lets say you are using a wire dipole fed directly with coax cable .... eg one side of the dipole is connected to the shield and the other side of the dipole is connected to the centre conductor. Lets assume your radio is grounded, either directly, or indirectly via the power supply. When you connect the coax to your radio the shield side of the dipole will have a DC connection to ground and any static charge that builds up on that half of the dipole will drain directly to ground via your radio ground. However the static voltage building up on the other half of the dipole appears on the centre pin of the coax connector and it can only get to ground via the circuitry in your radio front end and can can cause damage depending on the front end design of the radio.

Solutions:

If you use a balun at the feed point of the dipole the usual design will provide a DC path for both sides of the dipole. If you don't use a balun it is possible to put a high value resistor across the feed point of the dipole allowing both sides of the dipole to feed to ground via the coax shield or put the resistor across the feed point (coax connector) at the radio. In any case, the test is whether or not all parts of the wire antenna have a DC path to ground. Dipoles and long wire antennas are the major culprits as well as large vertical antennas. Loops are a little more

forgiving in that the wire is one continuous piece .... if any part has DC ground then it all has DC ground. A good ohm meter will tell you the story hi hi.

From: Dr.Ace Ratliff
Topic: 1551 Message: 1554

Hi Harold,
Any large bare metal antenna can develop a high static DC voltage charge unless there is a path to discharge the static to ground. Many times that path will be thru the receiver's front end. I know of several cases of this type of receiver damage.

You ask "Would your "static bleeder" work for dipoles too? " The answer is yes.
Large chokes connected from the feedline to ground will bleed off the static charges also.
You also ask "Do verticals avoid static accumulation or should they have a "bleeder" connection also? "
The answer is "that depends" on the type of matching system used. If the DC resistance across the station end of the feedline or at the antenna feedpoint , as measured with an Ohm meter , is a few ohms or less , you don't need to worry about a DC static charge build up. If on the other hand the DC resistance across the station end of the feedline or at the antenna feedpoint , as measured with an Ohm meter , is infinite , you should consider installing some type of discharge/bleed off device .
I hope this answers your questions.
P.S. Nearby lightning strikes can also induce very high voltages into large antennas.

Hi Jay,

No problem ..... I operated 20-15-10 mtr loops nested in both a driven element and reflector (cubical quad). No reason why there should be any problem with nested 40-20 mtr loops.

The story continues that one can sit there with a knife switch and flick
it back and forth and always get a consistant 300-volt pop time after time
after time, with no perceptiable rise/drop time between the pops.

Is reported to happen during windless days too.

Doesn't sound like static.

Hi,

What you describe is "BACK EMF". If I understand the experiment that produces the 300 Volt 'pop' is as follows:

-start with a large wire loop
-place a knife switch and some voltage measuring device across the feed point (an oscilloscope will do)
-flick the switch on (short the loop) then off (open the loop)
-the result is a voltage spike that peaks up to 300 volts

This experiment indicates that there is DC electron flow in the wire loop when it is shorted. When the short is removed, (flipping the knife switch), the sudden termination of electron flow causes a voltage 'pop' ... BACK EMF. The question is, what is the cause of the electron flow? Either the wire is picking up an electric charge due to environmental conditions or it is caused the Earth's magnetic field itself. No other way to get DC electron flow in a wire.

The following internet site provides a pretty good description of the BACK EMF phenomena.

http://www.newton.dep.anl.gov/askasci/phy00/phy00351.htm

DC or AC?

If it's DC, it'd be strange indeed to have it pop up to 300V and stay there.

If it's AC, then one would expect there to be 300V AC (or whatever value)
there all the time except when it's shorted out ... in which case, if you
ask me, it seems a wee bit silly to do that experiment with the knife
switch. (Kind of like toggling a wall switch and being surprised that a
light bulb turns on and off every time you do it.)

Regards,
Andy

Walter,
It seems you have a good knowledge in this sort of topic so how about being an Elmer to those of us that don't understand or just don't remember all that info; It is lists like this that is meant to share information amongst the members. I for one don't really understand how a wire that creates a DC short, can work for an antenna but is does. Members of this great group share their ideas, questions etc... with the whole group, that is why groups like this one is better than Radio Shack. At least here if some one has a question... they get an answer that goes beyond 'cell phones'.

Hello,
My name is Jim Lamb and I live in southwestern Indiana. I will be retiring soon and I want to get back into building radios and other electronic devices.
Several years ago I was an avid shortwave listener, I still have my Drake receivers,SPR4 and R4C, old but reliable. I got out my old radio parts and started gathering new information.
I want to get into longwave, mediumwave, and vhf as well as shortwave . I also want to experiment with antennas, dipole, vertical,etc.
I live in the country on 18 acres so space will not be a problem.
I am looking forward to participating in the group.

Generally you could work 30M and up. You MIGHT be able to work 40M. Better to see if you can put up a 40M loop.

Feed with 300 or 450 ohm ladder line, and use your antenna tuner. That will give you the most flexibility, and the least losses.

Hi Tom,

A 30m loop can be a very effective antenna for all bands 80-10M depending on how high you can get it .... It can be oriented horizontally or vertically .... or something in between. The loop can also be configured in 2 or 3 turns .... the single turn will be the most efficient. In order to tune the loop on all bands a couple of strategies can be employed:

The SGC (they make automatic antenna couplers) strategy is to put one of their automatic antenna couplers right at the feed point of the loop and to connect the coupler to the radio via coax cable. This is a very effective method of tuning such a loop.

The second strategy is to tune the loop with an antenna tuner located at the operating location ..... this requires running parallel feed line to the loop. 300 ohm twin lead will do a good job.

By the way, SGC recommends a loop 24.5M loop .... or 80 ft.

Hi Tom,

You are correct, the loop antenna operates dipole fashion in that it is a balanced antenna which does not require an RF ground in order to function properly. Being a balanced antenna the loop is best fed with a balanced feed line. However, as with the dipole, many operators feed a resonant loop with coax line with excellent results. In order to avoid or lessen antenna currents on the shield operators often use a balun or a simple RF choke (formed by coiling the coax feed line or ferrite cores) at the feed point.

If you are planning on multi-band operation then a balanced feed line such as 450 ohm ladder line is essential ..... unless you use an automatic antenna coupler right at the feed point (such as SGC weather proof units).

There has been a lot of discussion about DC grounding of loop antennas .... for safety purposes .... eg when lightning walks about .... or to simply drain to ground excessive static charges that build up due to various particles in the air etc .... These considerations are most relevant with really large bare wire antennas .... although under certain conditions even smaller antennas can build up sufficient static charges to cause damage to some radios. If you use a coax feed then then the loop is entirely grounded to your ATU/RADIO system via the coax shield. If you use a balanced feed system your antenna tuner may not provide a DC ground .... eg a link coupling system. In a case like that a high value resistor to ground can serve to drain the charge without contributing substantially to disturbing the tuning.

I believe it used to be common practice for hams to use a knife switch where the feedline enters the shack, and ground the feedline when not in use.

Perhaps it's something that's been semi-forgotten since changing to coax, since it's not so easy anymore to wire it up to that big old knife switch.

Of course the knife switch doesn't help while you're operating and the wind is blowing and the antenna is building up a few thousand volts of static charge.

Regards,
Andy

I'd expect the rigs of the "knife-switch era" were not as sensitive to voltage changes as the IC type rigs common today. Certainly the internal voltage ranges were much higher in tube rigs. Seems to me I've seen tube designs on the order of hundreds of volts. Whereas today's rigs are more on the order of 3 to 15 volts, depending upon which part of the internal circuits considering. Certainly different animals!

I know many of the tube rigs (all?) had a much greater tuning range than todays rigs due to the pi network they used to transition between the rigs output and the antenna.

I'm just guessing, but it seems reasonable to me to assume due to major design differences the tube rigs and todays IC rigs should be considered as separate categories most of the time. An interesting blending to consider would be those rigs that were half-breeds: part tube and part transistor.

I've also heard that "link" coupling was much more common "back then." As this eliminates a physical connection between the antenna system and the XCVR, it seems logical in these cases yet another safety barrior was in place between the antenna and the rig.

Anyone out there know for certain?

Hi Andy,

Years ago I had a large dipole fed with home brew balanced feed line and
that is exactly what I did when there seemed to be a storm brewing ... go
outside and pull the knife switch and put the feed line directly to ground.

Hi Erik,

Yes, my old tube rig was all home brew .... a 300 Watt plate modulated transmitter and tube type receiver. Both the receiver and transmitter had link coupling. The receiver front end band pass inductor used a link coupling to the antenna input. The transmitter used link coupling between the transmitter tank coil and the input to the antenna tuner. the antenna feed line was taped on either side of the tuned inductor and the link to the transmitter was mounted at the centre ... the link was also moveable to adjust coupling. Changing bands was not a quick operation hi hi.

The centre of the antenna tuner inductor was grounded as was the centre of the split stator capacitor. The knife switch outside was simply to put the antenna to ground when there was stormy weather ... or when I wasn't home hi hi ..

Keith, see the following link on the ARRL website;

http://www.arrl.org/members-only/tis/info/pdf/9908034.pdf

The article describes the mic (including the schematic diagram) and how to build a buffer amplifier to use it with modern radios.

Back in the mid 80s there was an excellent electronics magazine called Hands On Electronics. In the May/June 1986 issue was article by Ed Noll W3FQJ called Flexo SWL Aerial. I always wanted to try this antenna, now I will have the time and room to put it up. There are two problems, I have the original article but I don't have the correction for the control box that appeared in the next issue.
The second problem is I have looked all over the internet for Ed Noll or W3FQJ.
All I get are sites selling his books, no web or home address.
So, I need help. Does anyone remember the magazine and kept the article and correction?
Anyone who belongs to other groups will see this post again and again, etc.

Hi Tom,

First, the type of antenna you describe can be very effective and you will have no problem making contacts. I assume your MFJ antenna tuner has a built in balun to which you are connecting your 300 ohm feed line. Such an antenna will be close to 1/2 wave resonance at 40M, but since you are using 300 ohm twin lead you will have a mismatch ... eg approx 75 ohm to 300 ohm. On 20 meters it will represent a full wave and the feed point will be very high ... also representing a mismatch to 300 ohm.

I assume you are attempting to build a multi-band antenna in which case antenna resonance is not an issue ... in fact the antenna and feed line length are chosen to avoid resonance ..... especially 1/2 wave either side of the feed point ..... as in the 65 ft dipole you describe .... this will represent 1/2 wave either side of the feed point on the 20 M band. If you do a search on the internet you will find some sites that have researched ideal antenna and feed line lengths. 44ft (13.5M) and 88ft (27M) are a couple of favorite mult-band lengths as I recall. You may have to choose based on your favorite bands vs the available space for the dipole and the distance (feed line length).

Tom,
You may find Dr.Ace's webpage of interest on feeder lengths.

http://www.bloomington.in.us/~wh2t/zepp.html

"To avoid problems matching any center fed antenna with high impedance
open wire lines, keep the feedline around these lengths.

[The WORST POSSIBLE line lengths are shown in brackets]

160 meter antenna 35-60, 170-195 or 210-235 feet
[Avoid 130, 260 ft]

80 meter antenna 34-40, 90-102 or 160-172 feet
[Avoid 66, 135, 190 ft]

40 meter antenna 42-52, 73-83, 112-123 or 145-155 feet
[Avoid 32, 64, 96, 128 ft]

Some slight trimming or adding of feedline may be necessary to
accommodate the higher frequency bands."

Hi Tom,

Hi Tom, I have used zip cord as feed line with great success for portable antenna arrangements .... eg split approx 17 ft to form a dipole on 20M and then keep the rest intact as the feed line. I also use short pieces in my balanced feed line at home for purposes of running through bulkheads etc. There is no agreement .... and I have not measured .... the exact impedance of such twin lead .... nor it's efficiency. I am sure there is quite a range given the different line construction and materials used in different varieties of cord.

For portable use (50W or less) I have had great success with #16 or #14 copper speaker cord ... it is light and very flexible and seems to operate with good efficiency .... but I rarely operate with more than 50 watts .... usually in the 15 watt range. For purposes of running through bulkheads etc I have used more rugged lamp cord ... again #14 gauge variety .... and are only 3 or 4 feet in length.

If your purpose is simply to add some electrical length to your feed line outside I would recommend sticking to the 300 ohm twin lead ... it is reactively low loss and quite reliable .... even at higher power (150 to 300 Watts). However, I have never found any problem in mixing balanced line of different characteristics .... eg partially 450 ohm, partially 300 ohm, partially 100 ohm, etc .... however as I mentioned, the 300 ohm twin lead is a know quantity in terms of efficiency at RF. They used to manufacture 72 ohm twin lead for RF but seem to have discontinued it. Zip cord of different manufacture is always questionable for RF.

Hi Tom,

The key to an end fed Zepp is to keep the feed line 1/4 wave in length and the antenna wire a 1/2 wave in length. Your open wire feed line should represent an impedance close to the characteristic impedance of the line (eg 300 or 450 ohm) at the feed point ..... and it is balanced. The best way to feed 300 ohm with your tuner is to feed it via the balun in the tuner. The other end of the 1/4 wave length feed line will be very high impedance. The 1/2 wave length antenna wire which also represents a very high impedance at the end is connected to one of the two wires of the feed line and the other one is left unconnected.

In other words, you feed the balanced feed line like you would feed any other balanced feed line, with a balun (unless you have a specially designed balanced antenna tuner). The feed line is 1/4 wave long. Last, a 1/2 wave antenna wire is connected to one side at the high impedance end of the feed line. The system is basically designed for one band.

The end fed Zepp does not require an RF ground in order to provide a load to the antenna tuning unit. In order to operate properly the feed line must represent a high impedance at the end .... eg 1/4 or 3/4 wavelength. The antenna portion must be any multiple of a 1/2 wave length .. eg 1/2 or 1 wavelength. Small deviations in these lengths immediately introduces unbalance in the feedline and causes it to radiate. A Zepp designed for 40M will not work as a Zepp on 20M and vis versa.

If you want to go multi-band then you really have 2 choices ..... attach a length of antenna wire of equal length to both sides of the balanced line .... then when you go off resonance the feed line will not loose balance and will continue to act as a feed line on multi-band. In fact if you put a half wave on either side you will have what they call a 'Double Zepp' .... which is a really great antenna .... and it will no longer be end fed, but center fed.

Your second choice will be to simply tie both sides of the feed line together and treat the whole thing like a random length wire and feed it against ground.

The advantage of using an end fed Zepp with feed line and antenna wire of proper length is that you don't need an RF ground in order to feed it. This is especially handy for portable work .... or if you happen to be trailing the antenna behind your Zepplin air ship filled with flammable gas and you would rather not use it's airframe as ground hi hi.

1606. Smaller Skywire

Yahoo group: SkyWires
Date: 2006-04-26 18:24:25 UTC
From: Kyle
Topic: 1606 Message: 1606

As a bit of background, I passed my General exam back in November, and bought an ICOM-706 to use as my base station. I have been studying the code using a Gordon West CD set and a MFJ code tutor. I just can't seem to master it. Practice, practice, practice.... yet it eludes me.

Anyway, I am really excited to try a skywire, but can't do any HF work yet. So I started wondering if the skywire loop concept could be used on a smaller scale, a.k.a. a higher frequency like 2 meters. What does the group think? It shouldn't be a problem to mount it 1/4 wavelength or greater above the earth. If I have it greater than 1/4 wavelenth up, would it need an artificial ground below it?

If the members think it will (or might) work, I can do some experimentation. I just don't want to spend a bunch of time working on it if "it just doesn't work for VHF frequencies." I'm confounded enough with the code - I don't need any more frustration.

Oh, and I forgot to mention, I'd want to use it horizontally to keep it omnidirectional. Thoughts, ideas, suggestions?

From: D. Scott MacKenzie
Topic: 1606 Message: 1607

It will work just fine - although I would mount it vertically and feed it at the bottom to get horizontal polarization....you could also add another loop and make a quad. that way you could use it for SSB and CW on 2M. Cut it for about 144.150 or so. Remember to add the 1/4 wave 75 ohm matching stub....

I would mount it higher than 1/4 wave - that is about 2 feet off the ground for 2M. For VHF - the higher the better....

From: larry
Topic: 1601 Message: 1608

Greetings....

A question....

Your discussion about the 1/4 wavelength open wire feeder, I agree with however I am puzzled about one thing...

Your comment about using 300 ohm or 450 ohm feeder because it matches the end impedance of the dipole, has me puzzled....

My understanding is that the end impedance of a halfwave dipole is in excess of half a megohm.... At the end of a dipole you have your highest voltage and lowest current of the dipole therefore the impedance would be at it's highest..... hundreds of thousands of ohms impedance...

>
>Larry ve3fxq

Hi Larry,

Sorry to puzzle you hi hi .... yes, you are correct. A half wave length wire does indeed present a high impedance at the ends and low impedance in the middle. If you feed it in the centre the impedance is around 70 ohms. However it is possible to feed it at the end .... 'Zepp' fashion. Feeding it this way is usually done by feeding it off the end of a 1/4 wave length of open wire line .... the most commonly available line being either 300 or 450 ohm line. The half wave wire (usually horizontal) is attached to one side of the open wire line and the other side is left all by its lonsome eg end fed.

It seems to work .... that is the currents in the feed line seem to remain more or less balanced with minimum radiation. However, the antenna is a bit finicky. When the horizontal wire is exactly resonant the impedance (measured) at the end of the 450 ohm feed line reads between 200 and 400 ohms ... well within the range of an antenna tuner. Small changes in either the feed line length or antenna length dramatically effects the feed point impedance.

It seems like an odd way to put up an antenna .... however sometimes end feeding the wire is the most practical arrangement ..... especially this kind of end fed arrangement .... as it does not require an RF ground system.

Ken,

Great job on the loop. I have pretty much the same set-up here in southern Texas, but my loop is around 250 feet long and, at most, 12 feet off the ground. It loads up on 80-10 like a pro. Worked North Dakota this week on 75m using it. No complaints here. Wish I could get it higher, but that's not going to happen due to the restrictions, but no big deal. This is a great antenna. Good luck with yours!

If memory serves me, the D104 (aka Chrome Lollipop) is a 100~200k Z The fix is a rework of the high-low switch in the bottom of the mike stand. Search around on the ARRL QST for Astatic D104 fix. It has been a few years ago maybe 2000.

1619. Is a skywire loop a good choice to reach Mexico from Colorado

Yahoo group: SkyWires
Date: 2006-05-15 23:19:19 UTC
From: ransom_peek
Topic: 1619 Message: 1619

I would like to communicate on a vhf band from Fort Collins Colorado to Mexico and have not had much luck with a third floor attic dipole on 20 meters. I have covenants here, but a quarter acre lot might make for a good stealth skywire.

Is a skywire a good choice for dxing to Mexico?

1620. Re: Better Feed for 1/2Wave zepp

Yahoo group: SkyWires
Date: 2006-05-19 22:03:59 UTC
From: Pirate Paul
Topic: 1601 Message: 1620

If you can't resolve the feedpoint issue for the half-wave end-fed antenna, or don't like the results (because you have RF floating around all over the shack, or whatever), here is a different way to do it, and one that will allow you to use unbalanced coax and feed it the same way you would in the center (as a dipole). Done properly, you won't even need a balun, tuner, or RF ground to make it match the rig and perform properly.

```
---X---
|
|
---X---==============
```

As shown in the above pictorial of a horizontal J-Pole, add a quarter-wavelength tuning stub (---) to one end of the half-wave (===) antenna wire. Short the end (|) of the stub opposite the one connected to the antenna. Feed the stub at (X) with any coaxial cable 50 - 75 ohms. Find the correct feedpoint location by sliding the coax tiepoints (X) left or right. Note that while the total antenna length (---=======) is now three-quarters, it is still a half-wave antenna, as the tuning stub is not part of the radiating portion of the antenna.

1622. New to Group

Yahoo group: SkyWires
Date: 2006-05-22 18:27:26 UTC
From: Lee
Topic: 278 Message: 1622

Hi,

My name is Lee, callsign K3GI, living in southern Delaware. I've been using loop antennas for 10 years. I'm a newbie to the group.

My current loop is used for HF and has been up for about 10 years. It is cut for 80 meters (can't remember the length). It is strung from tree-to-tree in my yard with 6 supports. Height varies from 20 to 30 feet. I feed it with 450 ohm ladder line to a 4:1 balun with coax running into the shack. The automatic tuners on my Kenwood TS-850S and Icom IC-746 easily tune it from 80 to 10 meters (can work 6 meters on the IC-746). I've worked 50 states and over 70 DX countries with it, including Australia and New Zealand. I also use it for SWL with my Drake R8.

Originally it was fed with 300 ohm twin lead into an MFJ 949E for tuning into my Kenwood TS-440S which did not have the built-in tuner.

I've had other skywire loops up, but this antenna has been a mainstay. I hope to get up a 160 meter version sometime this year. The skywire loop is a great antenna, very versatile, and can work multiple bands if configured right. About three years I was able to put up a tower and beam for the higher HF frequencies (and VHF/UHF), but will never give up my loop(s).

73 de Lee, K3GI

1623. slopers

>Does any one have any info on building sloper antennas, or know of web
>sites for them?
> VE5HKC

Hi,

There are a number of sloper designs ....

--- A simple resonant dipole suspended with one end to the high support and
the other end tied off closer to ground ... and fed in the middle.
--- A ground fed wire antenna with the other end sloping up to the high support
--- A 1/4 wave wire fed with coax at the top of a steel tower sloping off
toward ground
--- An inverted Vee fed at the top
--- An inverted Vee fed at ground at one end

etc...

If you do searches on the internet you will find all kinds of versions
people have experimented with. Generally speaking I have found the sloper
seems to work very well .... I have tried most of them but my
favourite for effectiveness and ease of installation is a 100' inverted
vee with the apex at 30' made of 3 sections of TV mast. The two sides of
the inverted vee act as guy lines as well with a third of rope. Feed it
with 300 ohm TV twinlead to an antenna tuner and you will have an excellent
antenna 80-10 M .... once you learn the technique it can be put up in
about 20 minutes .... one person.

Jim, VE3CI

1625. balanced tuner design in QST March 1959

Yahoo group: SkyWires
Date: 2006-05-24 20:09:25 UTC
From: Dave Marling
Topic: 1588 Message: 1625

Recently I was looking through my HR Magazine CD's for tuner designs. In the July 1981, on page 31, W6SAI referenced in his article a tuner from the March 1959 QST.

Does anyone have either the QST article they could scan for me, or the article on CD that they email me. The drawings reproduced in the HR piece are very hard to make out. The article was by Lew McCoy, W1ICP. Lew also had an article in the November 1961 QST on a higher power version. I'd like a copy of that one as well.

Thanks,
Dave

Hi Dave,
Here's some info I hope you find helpful.

McCoy was well-known for one of his projects, ''The Ultimate Transmatch,'' an antenna tuner he described in a July 1970 Page 24 QST article.

SEE
http://www.miami.muohio.edu/president/personal/w8zr/homebrew/tuner.htm

Murch made a UT-2000 series of Ultimate Transmatch's , I have a UT-2000B

Reference :
``A Transmatch for Balanced or Unbalanced Lines,'' page 25-8 in The ARRL Antenna Book, 17th Edition, edited by R.D. Straw, (ARRL,Newington,1994).

Cedric VK4ZCL
> ---X---
> |
> |
> ---X---==========

Yes. The distance between the two Xs depends on the band. I use two inch (2" US) spacing on the VHF model which I built for my boat. Fahnstock clips at the two Xs allow me to slide the coaxial feeder up or down the solid heavy wire elements, to two pre-marked spots, which allows me to operate either 146 ham radio or 156 maritime radio band. A model I built for twenty-meters employs about a one-foot (1' US) spacing. I've built three of these (14 MHz) over the years, and all tuned up easily and worked great. I generally use a small, insulated stranded wire (about #20-guage) for all the elements.
Incidentally, you can ground the bottom of the stub (at the corner to the left of the lower X shown above), if it's convenient. That way, you can attach only half the stub (upper X above) to a grounded telescopic antenna mast or tower, for example, using stand-offs, and drive the grounded mast as a vertical antenna. Works equally well. Grounded antennas are quieter, and may present less attraction for lightning too.

It is. A virus (worm, actually), that is.

I've started seeing warnings about this worm, from places like Symantec.

It specifically targets Yahoogroups too.

Sometimes the sender's computer is the one that's infected, but sometimes it sends itself using someone else's (forged) address, probably grabbed from the address book on the infected computer.

Good morning, Skywires group. I have to say I really enjoy this group. There are a generous number of participants, activity is light, there is not a bunch of off-topic chattiness, and when posts are off-topic, they are at least of interest to skywire admirers.

Recently, we have been having a growing number of "spams". I ask if we should consider changing the group to require membership approval? My boss runs a Yahoo group for the accounting package we use at work, and requires applicants to tell him the version they are running and who their VAR is before he will approve them. Spammers see this and simply never apply. Users don't have a problem answering the question. He's had the group going for about 4 years now and not a single spam. In that time, the group has grown from 3 members to 28, which is exceptional for the small userbase it serves.

I would think we could ask potential new members to include their call sign and the make/model of just a single radio they own. A spammer would most likely move on, while a real amateur operator/potential member (even lowly tech class operators such as myself) would have no problem answering the two questions. While there are exceptions to every rule, the chances of a ham being a spammer seem low to me, as hams are not the type of people who would engage in such activity.

What does the group think?

73,
Kyle

In response to the message,

I myself have been signed up for a while now, but I don’t post all that regular. I apologize for this. One reason I haven’t is because I don’t have a suitable hf antenna at the moment. Also currently at the moment all that I own is a Icom 706MKII which I use on 2 meters mostly and 6 meters. As far as the callsigns go and equipment would be a good Idea I think. Hopefully as time progresses I will get my hf antenna up in the air and listen and post more.

Just my 2 cents worth.

Yahoo group: SkyWires
Date: 2006-06-16 12:14:41 UTC
From: Kyle
Topic: 322 Message: 1663

Keith,

I am a newbie, and have not yet got my loop up. But I did read something about this elsewhere on the Internet. If I recall correctly, a reflector is not needed because the typical 80m loop is < 1/4 wavelength (20m) up from the ground. At 20m up, on an 80m frequency the loop would have an optimal horizontal takeoff. However, most people have them far closer to the earth than 20m. Although this turns the takeoff angle more vertical, because of the inherent efficiency of the design, there is still plenty of signal towards the horizon for DXing. Putting a reflector wire underneath the loop would do nothing if it were physically on the ground, and putting it in the air exacerbates the issue, making the takeoff more vertical. As I understand it, the reflector wire would only theoretically help if your loop was greater than 20m off the ground. So the bottom line as I recall was that is really wasn't necessary. Perhaps someone in the group has tested this and can shed more light on the subject.

And please correct me if I am wrong!

I've been told that the most effective solution to keeping spammers out of Yahoogroups (even better than requiring membership approval), is automatically putting all new members on 'moderated' status, until they post at least one valid on-topic message. Moderated status just means that if they post a message, the message is delayed until approved by the moderator. After that, the moderator switches them to normal status and subsequent messages aren't delayed.

Requiring membership approval has the advantage that spammers don't get to even join and harvest names and addresses from the messages they receive.

And it probably helps to hide the list of Members (especially if the group doesn't require membership approval). The Member list is a great resource for spammers.

I manage two lists on Yahoo. They are set up so any new application comes to me for approval. If I'm at all suspicious I send a request to the applicant from a throwaway account on Yahoo. If they reply with their callsign (or with a legitimate reason to join) I check them out on the databases, and if they pass, I approve them. If not, they're gone! Most, if spammers, won't bother to reply.

I'm also a co-manager for the qrp-canada reflector and do the same for it. There, we ban any spammer making application, although most lately seem to be sending unsolicited mail rather than trying for entry, so it gets held for our approval/rejection. Then we place them on an auto-discard list. That site uses different software and has more options about what to do with these folks.

My opinions...

Yeah... the worst thing is so many members take the bait
and reply to the spam asking to be removed from the list,
thereby validating their email addresses. The spammers sell
(or trade) their lists among themselves.

A guy who sublets space in my office had real problems because
he kept responding to the option to "go here to be taken off"
the list. Doing this, he had picked up more than a thousand
instances (each) of various viruses and spy ware cookies.
He has had only two or three since we got him to stop doing this,
and use a decent anti virus and anti-spy ware program. Now, if we
could only get him to quit using AOL, we would allow him to access
our network...

Just my take. /////////// Richards ///////////

When we moved to an antenna restricted neighborhood more than 15 years ago (as in no outside antennas) I put a 40m loop in the attic, fed with ladder line down thru a wall and to a
current balun in the shack. Worked pretty well. Then I moved the antenna outside. Another 40m loop--in sloping delta configuration, again fed with ladder line, balun and coax to shack--It equalled the attic loop. My final loop is 80 sloping delta with the apex up about 50ft in a fir tree and the baseline up about 5ft along a cedar fence. It is fed in the corner
with a 4:1 balun and coax to the shack. The antenna wire is #16 copperweld which is practically invisible, at least to retired folks' eyes--like mine. But have not had a complaint.
Hardly ever work 80m but have made many a stateside and DX contact with this antenna on all bands 40m and up. Fairly low SWR on the resonant bands and tuner takes care of the others.

Love the loop!

Basically,
Baluns wond on PVC pipe require a lot more turns of wire to adequately
do the impedance change or balance. For that reason we use ferrite
type material that has a frequency response within the bands we use.
It therefore requires a lot less turns to do the job because of
the "Permeability" of the ferrite material.
If the balun is wound on an iron core it saturates at very low
frequency and is not usable at Ham frequencies.

Comment... The term of "a lot more turns" may be overstated. I build lots of air core baluns for 1:1 matching at HF. I use 3/4 inch PVC for the core and it only takes 10 turns of triflilar wound wire to do the job. I prefer air core because it does not saturate or overheat as easily a ferrite. Just the opinon of this ham.

Richards,
That loop antenna works well on 40 M using low power like 5 or 10
watts. It seems to be as good as my G5RV which is at 40 ft and the
loop is sitting inside the house as shown in the pics.
Bandwidth is narrow though and you must fabricate a tuning capacitor
or even make the loops open like the pages of a book.
Watch out, even with low power you can get nasty burns from this
antenna if you touch it while transmitting.
It blistered a large spot on my forearm and it took months to heal.
I wonder if it could be used to cure hemmeroids?

1683. Another Newbie With A Question

Yahoo group: SkyWires
Date: 2006-06-26 17:21:01 UTC
From: MD Calvert
Topic: 1683 Message: 1683

After fifty years of on-again off-again listening to SW, I am trying to get back into the fun. I Googled various terms through groups and found several. I joined this one because of the idea that I might FINALLY begin to understand a little more about wire antennas.

In looking at the photo files of various SkyWire antennas, I noticed that almost all involved a wire loop of some shape and length, connected to a coax feed line by a "matching transformer." I don't know what a "matching transformer is, looks like, or does. Can someone post an explanation with pix of a transformer (or several if they differ in size, shape, etc.).

Thanks all,

MDCalvert

Hi MD,
Welcome to the group . It is not necessary to connect a Balun / matching transformer between the loop antenna and the feedline . Some people use a 2:1 balun between the loop antenna and the feedline . A full wave loop antenna should have an impedance of about 100 ohms so a 2:1 balun provides a good match to 50 ohm coax .

Baluns / matching transformers come in various types .
Here's a link to one I designed
http://www.bloomington.in.us/~wh2t/balun.html

Check out
http://www.bloomington.in.us/~wh2t/loop.html
for some info on loop antennas .

A good choice of groups!

> In looking at the photo files of various SkyWire antennas, I noticed
> that almost all involved a wire loop of some shape and length,
> connected to a coax feed line by a "matching transformer."

The word "Skywire" refers to a horizontal loop antenna. This is why you are seeing so much discussion about this type of antenna. This group formed to specifically discuss that type of antenna. You generally won't find us discussing dipole, verticals, beams, or just about any type of antenna except loops, unless in passing or by way of comparision to loops.

"Matching transformer" could mean several things.

Unfortunately, often in the amateur radio community terms are used to mean more
than one thing, and at times we don't agree on the proper use of such terms. In
that light, it is a hobby after all, so you can't expect to hold us to the same
standards as a professional group. On the other hand we do try to come to a common use of terms.

Most likely this term refers to a length of parallel transmission line connected
to the feed point of the antenna, the other end of which is in turn is attached
to a random length of coax. Typically there is a balun at this junction between
the two types of transmission line.

Hope this helps a little bit,
Erik n0ew

The following is based on theory, as opposed to experience; but I think a reflector also helps because real earth tends to be lossy (unless you live by a salt marsh).

Also, it's not the top of the soil that reflects, it may be several feet down and somewhat ill-defined, so a reflector loop or wire can help give your antenna a better defined reflector with a known separation.

From: Karel ZS6WN
Topic: 322 Message: 1693

Hi Andy and others

I've playing around with skywire loops for many years (since the invention of the german quad in the late 70's..) and the idea of having a reflector loop has been going around in my thoughts for a while.

Now I wonder: should it be the same size as the main loop, or shorter or longer?

And what would an ideal separation be?

Another idea was to have a smaller loop inside the main loop at the same height.

Wonder if the guys with the fancy antenna analyzing software can't shed some light for us on these?

I kinda had a similar idea to this one.....

My thought was to try a loaded loop about 1/3 smaller inside the larger loop and feed it out of
phase to the main loop.....

My hope would be to act some what like the phased feed on a beam and direct more of the signal outward....especially on the lower bands....

Not having the software to model it and City not letting me put up a loop to try it, no idea if it
would work....

I've read that the reflector loop should be a little larger. Same as the reflector on a beam. Making it longer/larger makes it inductive which gives it the optimal phase shift, or something to that effect. (How much larger? 5% or so??)

> And what would an ideal separation be?

According to what I've read others say ... Some say 0.25 wavelength is ideal, while others say that is only theoretically true for a plane reflector (which it ain't), and something more like 0.1 or 0.15 wavelength gives the best gain / best results.

Andy

1696. Size of horizontal loop?

Yahoo group: SkyWires
Date: 2006-07-29 16:55:12 UTC
From: Hans Remeeus
Topic: 322 Message: 1696

Dear all,

Next year we will move to another house with a yard of about 1 acre.
After 35 years of dipoles finally a horizontal loop is within reach!

My most used band is 80 meters for local and mid-European communication.
A few times a year I participate in an HF-contest, but I am not a kind
of DX'er.

I want to feed the horizontal loop with about 200 feet of 600 Ohm open
line and use the loop for multiband 160 - 10 meters with a balanced
antennatuner.

The height of the loop will be about 35 feet and I will use wooden
supports for the loop.

It am planning to make a full-size loop for 80 meters. However, on this
yard it is easy to make a loop of 4 x 100 feet instead of 4 x 70 feet.

What is your opinion about the size 400 feet instead of a full-wave for
80 meters?

Thanks!

There are members a lot more qualified to answer than I, so consider this only an opinion, if you have the space to add a little more than a hundred feet, it would be close to being resonate for 160 and still work on all the others.

I have one that is about 530 (ish) feet and at best maybe 20 feet up, and currently supported in and around trees, when I first put it up I could tune it in to use it on 160, right now I can't, one of these days I will get around to trying to see why I can't tune it in, but for now I can use it on 80 on up through 10 if I want; almost forgot I have about 20 or less feet of RG8 coax directly connected to the loop. Maybe if I experimented a little I might get it to work better, but for now it does what I want it to do.

From: Dave Marling
Topic: 322 Message: 1698

I took the lazy way when it came to the first loop. I bought a 500' roll of #14 electrical wire at Home Depot and used the entire length, adjusting the support lines over the convenient trees.

A couple of years ago, I thought bigger might be better so I added another 500' roll to the first, moving the support lines out to other available trees.

One night, I got around to running the configuration through EZ-NEC and found the direction I wanted to favor actually had a small null. Plotting the original 500' version gave me a slight bit of gain where I wanted it.

So, down came the extra wire, and back to the original trees for support.

Mine is five (unequal) sided as that allowed for a more open loop than with the four points available.

Fed with open wire line from a homebrew ballanced tuner.

Thanks to all for your nteresting information!

This evening I found another interesting site about large horizontal loop antennas, including a very simple but effective tool. It can be found on http://www.smeter.net/antennas/rjeloop4.php

I will make a horizontal loop of 4 x 25 meters (= 4 x 82 feet) for 160 - 30. And for the higher bands a 14 MHz full-size vertical delta loop. Both with open feeder line.

Karel-Ou Klein Boet,
When I operated from ZE as ZE1FF in the 70's I had a 20 meter 4 element delta loop beam hung from a catenary rope suspended between two trees. The direction was fixed of course.
The spacing between elements was the same as you would have for a regular yagi and the element size was +5% for the reflector and corresponding reduced sizes for the directors.
At one point I changed the feed and fed all elements like a log periodic. I eventually had to take it down as it was making my wifes bedroom flourescent light flicker on and off.

I've had a 80m slanting delta loop of 16 guage copperweld up for over 10 years without issue. It has gone thru ice storms and pretty high winds. Wire doesn't stretch. It is also fed thru a 4:1 current balun and coax. I've been very happy with this low profile antenna --especially since our CCand R's prohibit any outside antennas.

I'd go with the stranded wire. This antenna will be outdoors, so I'd prefer to have the greater durability of stranded wire to survive the swaying in the wind.

You'll also get slightly wider bandwidth with the larger diameter, but the two choices are so close to one another you likely _won't_ notice any improvement.

Of course, if the single strand is free, and you don't mind occassional repairs, you may go that route.

How's that for a non-answer! Hehehe....

You're also likely to get a number of sugesstions regarding balanced transmission line of one type or another. Less loss. Important? Depends how long your run of transmission line is, and how much you care to be watchful of keeping the balanced line away from metal.

Whatever you choose to do, it'll likely work pretty well.

Dan:
I always use insulated 12ga stranded wire for my antennas including my 75mtr delta loop. Cheap if you buy at Home Depot or Lowes.

I dislike copper weld, harder to work with.I DISLIKE solid wire of any kind including solid wire open wire feedline, always use stranded wire for any antenna use.

12ga stranded will stretch a little, but I use open wire feeders and a tuner so dont worry about it. After a couple years it doesnt stretch anymore.

I have a 130 ft zepp with stranded wire, been up 6 years and thru many high winds and several ice storms, the wire is tuff.

I have an A-99 and I have not used it for a few years. Yesterday I got it out and checked it out. I noticed that it seems to be grounded. What I am saying is, When I checked the end of the plug to screw on the COAX I noticed that my meter showed that it was touching somewhere. At first I thought that it was my COAX but I figured out that is was the Antenna. I took the antenna apart and checked and could not see a visible problem. I did not fully take it apart to where it could not be repaired and put back together. Does anyone know what could be wrong? I have never built an antenna so I am not very good in this area. I di know how to work on C.B. radio's but not antenna's.
Thanks,Dean

Hi Dean,
The antenna is probably designed to be a DC short to ground but not a short to ground at RF . Check the VSWR .

Hi

YES that antenna is DC grounded !

http://www.walcottcb.com/solarcon-a99-base-cb-antenna-ground-radial-kit-p-1012.html

Measuring with an ohm meter from the inner of the coax to the outer
braid will show up as a short circuit.
It is not actually zero ohms , but very very low at DC.

This DC grounding is normal , part of the design and is there to
provide a level of lightning protection by providding a low resistance
path from the antenna active element to the supporting structure (pole
etc)
It is often used on external antennas like this.

Thank you very much. Now I can put it back together and use it.
This will save me a lot of money. I am used to the mobile antenna
more than the Base antenna. I did not find the fine print about the
DC ground until you pointed it out for me. I looked all over the
Web, before I thought about looking here.

I thought that I repaired this antenna. I took it apart and only changed the coax and made sure that it was put back the same way. I used some clear hose in place of the little piece of plastic that they had keeping it seperated inside. I had to use a PVC repair tube that basically just joines PVC together and it had a piece of rubber in it. I do not see what this could change. It seems like the PVC does not really do anything but help provide length. I could be wrong on that matter. Like I said before, I am just learning about Antennas and do not understand all of the math behind it. I have already ordered a new Procom PT-99 and it will be in here in a couple of days. It did not really cost much to basically look inside of this one. I do not know how to check for the D.C. ground. It seemed like it was not grounded after what I did. I do not know anything that I changed. The copper wire inside of it rattles a lot so I think it was damaged before I even started. I am hoping to find another base to replace the base on this one.
The main reason that I took it apart in the first place was because when I was putting it together the first time, the bottem was turning and it is not supposed to turn. While I had it apart I noticed that where the COAX inside of the bottem was soldered, had came unsoldered. There was no way to repair this but to take it apart. I think that someone played with it because the tuning rings were turned all of the way up and I almost did not get them loose. I guess I know now what the inside of one looks like.

Thanks for all of the help. I put a little information on another site and got called stupid. It seems like the people here really try to help.

The wire in each section is not held in place by anything other than the conection at top and
bottom, so it will rattle around when shaken.

This is normal and not a sign of damage.....

The wire in each section is not held in place by anything other than the conection at top and
bottom, so it will rattle around when shaken.

I noticed the same phenom in the bottom and mid section of my Solarcon. Among many other things I got this Solarcon in a big trade a couple of years ago. At the last minute the other fellow said here take this I no longer need it. I was going to put it up. But first I decided to do something with the 2 sections that rattled. Long term I suspected this situation could take a toll on the connections at either end with wind shaking it. Here is what I did. I drilled some holes in areas that had nothing in them but the wire. Mid section was easy, as that is all there is but a wire from end to end. But the bottom section is a different story. Anyhow I found this Article about the 99 on the net:

http://www.marktruett.com/files/a99.pdf It loads slow but has decent fotos as to internal parts locations.

Although it did not talk about my thought to cure the rattle it did show a 99 cut apart and allowed me to drill safely.

Important Note:

Care should be taken to ensure the bit does not grab and pull in hard as it breaks thru the inner wall as to not cut the wire. Better a rattle than a chopped conductor. I clamped my sections in a drill press mounted machinists vise just enough to hold it firmly while I drilled.

After drilling the 3 ¼ holes each in both sections. (¼ inch was just right to allow the nozzle in the can to slip in. I did not use the extension tube provided.) I squirted in a dose of DOW GREAT STUFF. I stopped just as it started to come out of the end holes. I inserted the GREAT STUFF nozzle into the center hole. As far as I could tell it reached the escape holes at the same time. All 3 holes seemed to weep out the same amount of expansion excess. This is an insulating foam sealant used as an expanding weather proofing. It does that real well, Hence the appropriate name "GREAT STUFF" I have used this stuff before and it expands like crazy. The first time I used it was under a sill plate on a prehung exterior door. Well it did not have sufficient escape for the expanding characteristics. It bowed the aluminum sill. Had to get a new one. But anyhow I filled both section and placed them in the sun horizontally holes downward. It expanded rapidly for about 30 minutes or so. Then just slowly oozed for an additional hour. The wires no longer rattle. I trimmed off the hard

foam that was sticking out and touched it up with a bit of F'glass resin just to be sure it was sealed from the weather.

Disclaimer:

I am in no way suggesting that anyone do this. Experiment at your own risk. This writer will assume no responsibility for any attempts to stop Solarcon 99 rattles that may be inspired by this posting.

This antenna is truly an extra and its destruction from this crazy attempt will not upset me. So I figured it was worth a try. Once I get it up and load it up, I will report, Very, very briefly as to if any electrical effects from the foam rattle repair attempt occurred.

1722. Re: Putting new loop up.

Yahoo group: SkyWires
Date: 2006-08-13 23:30:01 UTC
From: joey98223
Topic: 1703 Message: 1722

OK, one more question with my loop up and balun installed the SWR ratio is showing that the anntenna is long, ergo at lowers frequency for band SWR is lowest.

SWR for loop @ 3505 is less than 1.5 it rises as the frequency increases to over 3.5. This swr exhibits itself on both 40 and 75/80 meters.

By checking my desired optimum freq 3900 on 75/80 meters i feel that i need to shorten the loop by approximently 9 feet, I hate to remove this much wire at once but dropping the antenna and reterminating the wire at the feed point is a lot of work.

I was wondering if I could take a section out of the loop near the center of the antenna and resolder the wire ends and still have it preform as a loop antenna?? But I am worried that this might cause an inductive loop that would change the anteena characterists<SP> too much.

Any suggestions for this problem?

Thanks in advance 73's

Dan

I am glad to talk to someone that has taken one of these apart before. I cut mine into. This is the only way to get the bottem off. I did not correct the problem and it is not DC grounded anymore. That was not a good thing because I have found out that it has got to be DC grounded. The bottem connection keeps spinning and I soldered the hell out of it. I gave up on it for now. It was a bitch to put back together. I had to use a PVC pipe connecter to put it together and it did not want to join. I used the connecter that has the rubber in it that wedges it together if you know what I mean. I did put some thicker clear hose in the place of the small thin piece on the inside that kept it from pos and neg from touching. I do not know if that stopped the DC ground or not. I do not see why it would since they had it that way to begin with. I would be willing to try to construct the entire thing (bottem half) myself if it did not cost so much. It is not made of much
but fiberglass/pvc pipe. I can buy another antena at my dealer price for around $50.00 that is the same antenna (Procom PT-99). I already bought one and it seems to work great. It would be great if I ran across someone that had a bottem piece without the top. Let me know how your project goes.

Thanks,Ga.Slim

1724. Re: Putting new loop up.

Yahoo group: SkyWires
Date: 2006-08-15 20:03:20 UTC
From: Karel
Topic: 1703 Message: 1724

Hi Dan,

This antenna in my opinion and experience is very forgiving. I played around with it a lot over years and it remains my antenna of choice for multipurpose use.

I use a 160m long loop (so roughly 4 x 40m square). I have more than enough space for it or even bigger loop. Its been up for 2 years and I worked over 230 countries with it so far, including 25 on 160m.

The one problem I had was to get it to resonate on our limited portion of 160m (1810 - 1850KHz) but still be able to use it on 80 and 40 and the rest of the bands. If the SWR is lowest on 1825, it will obviously be the lowest around 3650 on 80 (OK for local use but not DX) and 7300 (useless for me as our 40m is 7000 - 7100).

Yes I do use an ATU but as you know that create losses which is not always acceptable.

So if I want to work DX low down on 80m around 3510 it means I must lengthen the antenna so it resonates around the bottom of 80 but it will result in it to resonate around 1755kHz.

What I did is to take little choc block terminal connectors, cut the loop somewhere at the opposite end and add a extra length of wire for 160m use or simply take it out and "screw" the shorter loop together for use on the bottom ends of 80, 40, 20, 15, 10 (and the rest of the bands through the ATU).

Hope this helps. I suggest you just go for it!

hi everybody,

my idea is to make a skywire, but my perimeter
lenghr is circa 30m (not multiple of 21).

My loop should be all 30m conductors (by electrical
coil 1.5mm) or only 21 m shold be electrical and the rest
9 m made by nylon ?

The setup is preferrd in orizontal plane 2/3 m up, or with inclination to gruond ??

tanks a lot from now

1726. RE: Putting new loop up. -> W%DXP's No-Tuner Tuner

Yahoo group: SkyWires
Date: 2006-08-16 19:52:12 UTC
From: Ronald C. McConnell
Topic: 1726 Message: 1726

Karel, says about his big loop,
"...The one problem I had was to get it to resonate
on our limited portion of 160m (1810 - 1850KHz)..."

Take a peek at Cecil Moore, W5DXPs "No-Tuner Tuner"
approach where he switches in lengths of low-loss
open-wire feedline in binary steps at the transmitter end
of the feedline to transform a nasty impedance into a range
where the tuner, or even the transmitter itself, can handle it.
No magic, just transmission line theory and practice...

< <http://www.qsl.net/w5dxp> http://www.qsl.net/w5dxp>

For portable operation, Cecil says,
"I carry around 1, 2, 4, 8, & 16 foot lengths of 450 ohm line
and just plug them together with banana plugs to achieve
a match without a tuner."

In particular, see

W5DXP's No-Tuner, All-HF-Band, Horizontal, Center-Fed Antenna

< <http://www.qsl.net/w5dxp/notuner.htm>
http://www.qsl.net/w5dxp/notuner.htm>

which shows the whole base station antenna
= 130' centerfed dipole + 450 ohm feed + "No Tuner" Tuner
and a fixed version of his "No-Tuner" Tuner
with data, photos, ...

Maybe for 160m, you could add a 64ft section,
if 32 feet isn't enough.
(Hmmm, do the arithmetic...)

Cheers, 73,

Ron McC.

Dean Terrell <tandn_family_electronics@...> wrote: I am glad to talk to someone that has taken one of these apart before. I cut mine into. This is the only way to get the bottem off. I did not correct the problem and it is not DC grounded anymore. That was not a good thing because I have found out that it has got to be DC grounded. The bottem connection keeps spinning and I soldered the hell out of it. I gave up on it for now. It was a bitch to put back together. I had to use a PVC pipe connecter to put it together and it did not want to join. I used the connecter that has the rubber in it that wedges it together if you know what I mean. I did put some thicker clear hose in the place of the small thin piece on the inside that kept it from pos and neg from touching. I do not know if that stopped the DC ground or not. I do not see why it would since they had it that way to begin with. I would be willing to try to construct the entire thing (bottem half)
myself if it did not cost so much. It is not made of much but fiberglass/pvc pipe. I can buy another antena at my dealer price for around $50.00 that is the same antenna (Procom PT-99). I already bought one and it seems to work great. It would be great if I ran across someone that had a bottem piece without the top. Let me know how your project goes.

1728. Feeding the Loop

Yahoo group: SkyWires
Date: 2006-08-18 15:25:42 UTC
From: KR Mason
Topic: 1728 Message: 1728

Greetings group,

I'm going to put up my first outside loop this weekend. I've played with one in the house (thumbtacked to the ceiling) and really liked it. I'm excited about getting one up outside.

My plan is to feed it with homebrew parallel transmission line to a 1:1 current balun at the shack entry and then coax from the balan to a homebrew l-tuner. I understand that the l-tuner is not a balanced tuner but am hoping the balun will make it work. The coax from the balun to the tuner is less than 3 feet. Is it a reasonable expectation that this will work? I'm thinking that the short run of coax will keep losses to a acceptable level.

Any comments and or suggestions will be appreciated.

Thanks,
Kent

Kent, that certainly should work. What is the size of the loop? For example, a 40m loop is about 140' in length. It will exhibit a fairly low SWR on resonant frequencies and line loss
should be quite small. I have a fir tree in the yard and have strung the apex of a 80m slanting delta loop from there. It is fed in a bottom corner with a 4:1 current balun and then about 40' of coax to the shack. Works fine.

Have fun, Gary W7TEA

Hi Mel,

I feed my horizontal loop with commercially available ladder line (110 ft. in length) and a W2DU balun at the shack end of the transmission line. From the balun I use 20 ft of coax to a Ten-Tec tuner which is an L network tuner with an unbalanced output.

The loop is 270 ft. in length. I operate it on 160m to 10m.

I recommend using a current balun (like the W2DU) and NOT a voltage balun.

Good balun article: "Baluns: What they do and how they do it" by Roy Lewallen. Use Google to find the paper. Lots of good words and measurements in this paper.

Also on the web you can find the balun chapter from the book Reflections, written by W2DU, on the W2DU web site.

Good luck and have fun.

Hi Kyle,

Thanks for looking up those URLs for the group.

With respect to Baluns: It is interesting to note that some authors are proposing placing the current balun at the INPUT side of the antenna tuner to obtain optimal performance. I have not investigated this unique antenna circuit topology. This is briefly discussed in the W2DU reference below.

I highly recommend the book Reflections by W2DU. I've learned more from this book than any other I've read. It can be purchased on the ARRL web site.

If you like to experiment with ferrite cores, the cores are readily available from the Mouser Catalog. The Mouser web site is excellent. They carry a wide selection of clamp on cores and solid cores. Make sure the resonant frequency of the cores you are purchasing agree with the bands (HF vs. VHF vs. UHF) that you are operating. Also, Mouser does not require minimum order $$-- Digikey requires a $25 minumum order.

73s,

Bob/WB2UFE

have you tried asking your local library to obtain that publication through interlibrary loan services? Although it is not the sort of thing that all libraries readily have on the shelf, these services can tie into collegiate and other specialty libraries which would have such a thing on hand. Many colleges have amateur radio clubs, and their libraries might have such books, therefor. I find a lot of books, CDs, DVDs, videos, etc. this way, which would not normally be in the stock of my local library. Usually, the service is free. This service might get you the book on a temporary basis, while you look for your own copy to purchase some place or other.

Just my take. //// Richards ////

1743. Best Antenna Ever...

Yahoo group: SkyWires
Date: 2006-09-05 03:29:08 UTC
From: JimMcSkate@aol.com
Topic: 1743 Message: 1743

My 40m loop blew down in Saturday's remains of TS Ernesto, which hit Long Island with gusts up to around 40 MPH. on Sunday I replaced it completely - new wire, new supports (one was saved - the rest broke in the storm). Took about two hours, with my 5 year old helping... if he hadn't been helping it would've taken about an hour.

Total cost: zero. (I happened to have a few hundred feet left on a spool of insulated stranded wire, and made three supports out of scrap lumber.)

Best antenna ever. EVER!

EUROPEAN AMPLITUDE MODULATION AMATEUR RADIO GROUP

NEW YAHOO GROUP: http://groups.yahoo.com/group/eamarg/

This is a group for licenced amateur radio operators (HAMs) who are interested in the AMPLITUDE MODULATION (AM) mode of communications. The group exists to promote the AM operation in the HAM bands and provide information about operating events and technical matters.

EAMARG encourages regional AM activity insuring there is AM available somewhere on the amateur bands. Based on the fact that the majority of the AM calling frequencies in USA belong outside the european HF bandplans... one of the EAMARG main goals is to help in the establishment of AM calling frequencies that will be compatible with the HF bandplans of the european countries.

EAMARG future plans including the sponsorship of operating events and contests that will promote the use Amplitude Modulation.

In order to join this group you must be a licenced radio amateur.

1752. 160m loop design

Yahoo group: SkyWires
Date: 2006-09-14 20:07:56 UTC
From: Mike
Topic: 1752 Message: 1752

Hi,

I'm glad I found this group after searching eham. I have a few design questions about building a 160m loop for multiband use.

1. Which feedline to use 300 or 450 ohm ladder line?

As per Dx Engineering 300 ohm is better because the impedance swings wont be as great seen by the tuner.

2. Which balun to use, 1:1 or 4:1.

As per Dx Engineering the 1:1 balun is the choice again because the tuner will not see a very low impedance.

3. What length should the wire be?

I believe this depends on the gauge of the wire and whether or not it is insulated taking into account velocity factor.

Choosing a balun by DX Engineering gives different answers on which balun to use depending on usage.

Tnx,

Mike KA2FIR

Topic: 1752 Message: 1753

Hello Mike,

I recommend to read the excellent site of W4RNL:
http://www.cebik.com/fdim/atl1.html
http://www.cebik.com/wire/horloop.html

Another good article is:
http://www.smeter.net/antennas/rjeloop4.php
This site contains a very nice tool.

I am planning to install a 1/wavelength 160m loop next year spring. With homemade open feeder line from the same wire as the loop. This would be around 600 Ohm.

1. Preferable is 450 Ohm or more.

2. 4:1 or 2:1.

3. The loop 1/wl. The length of the feeder is not very important, so is the velocity factor and the gauge. I would prefer an insulated wire of at least 2,5 mm2 (AWG10?).

Good luck!

Hi Mike ,

I agree with Hans. 450 ohm ladder line is better than 300 ohm.
A 4:1 balun should perform better than a 1:1 balun.
I would make the loop from about 530 to 560 feet of wire.
You can use bare or insulated wire. I would use a heavy enough gauge of wire that it wouldn't break very easy. My 75/80 mtr loop is made from 272' feet of solid, bare, 8 AWG wire.
Here's a page where I show how to home brew a 4:1 balun - http://www.bloomington.in.us/~wh2t/balun.html

Subject: [SkyWires] 160m loop design

Hi,

I'm glad I found this group after searching eham. I have a few design questions about building a 160m loop for multiband use.

1. Which feedline to use 300 or 450 ohm ladder line?

As per Dx Engineering 300 ohm is better because the impedance swings wont be as great seen by the tuner.

2. Which balun to use, 1:1 or 4:1.

As per Dx Engineering the 1:1 balun is the choice again because the tuner will not see a very low impedance.

3. What length should the wire be?

I believe this depends on the gauge of the wire and whether or not it is insulated taking into account velocity factor.

Choosing a balun by DX Engineering gives different answers on which balun to use depending on usage.

Tnx,

Mike KA2FIR

1769. Whidbey Kite fest ops Sept 23/24

Yahoo group: SkyWires
Date: 2006-09-17 18:38:11 UTC
From: icra@galaxynet.com
Topic: 1769 Message: 1769

Have confirmed permission to operate from the annual Whidbey Island Kite festival.

Scheduled to run Sept 23/24 from 0900-1700 (1600-0000GMT) each day.

With reasonable winds, will be on kite lifted antennas.....taking a modified multi-band vertical just in case.

I will be there, but may have a few others show up to operate, so calls may vary through both days.....intend to have Whidbey Kite fest included in the CQ broadcast.

At this time, plan to focus mostly on 20mtr SSB with some attempts at 40mtr SSB. May have some 30mtr PSK31 if I can get the laptop working with it or some one brings/loans gear for it.

Would really love to work others that are flying antennas, so if any one is interested and able, go out and fly a kite lifted antenna on those days.....others in the local kite club would get a real thrill from it....might be able to get them interested in ham radio....

Will post more details on the event plans toward the end of the week...

1770. Bazooka for 160?

Yahoo group: SkyWires
Date: 2006-09-17 19:42:15 UTC
From: AD5VJ Bob
Topic: 1770 Message: 1770

Well I sent this to TopBand Reflector first but no one has responded so I guess I stumped 'em.

Hello everyone:

I am in a space limited environment and already have a double bazooka tuned for 80 meters that works fine on 80 meters. I also have
a MFJ-949B Tuner and a manual antenna switch. Rig is an IC-775.

I have two antennas already going to the MFJ the double bazooka and a TitanDX Vertical. Therefore both PL-259 connectors are being
used.

I do have a random wire input to the tuner and a balanced wire input that are open at this point.

Does anyone know of a way I can use the Double Bazooka tuned for 80 meters (or something) at least for stateside work on 160.

I realize that DX would be out of the question without, A LOT OF HEIGHT, a Vertical, Loop or Beverage, but those are not options for
me at this point.

My only chance at this point is to somehow use the Bazooka for local calls.

Someone somewhere had said something about shorting it but if so where and how?

Hi Bob ,
You could try shorting the coax center and shield together at the station end of the coax and then try feeding the antenna as a top loaded vertical. It might then be tunable with the MFJ-949B on 160 mtrs. Make sure you have a good ground at the MFJ-949B .

1772. RE: [SkyWires] Bazooka for 160?

Yahoo group: SkyWires
Date: 2006-09-18 00:01:32 UTC
From: AD5VJ Bob
Topic: 1770 Message: 1772

Hello Dr:

Well I tried that and it seems to tune but if I try more than about 12W output the rig abruptly turns off in such a way that I dont
want to do that anymore.

I checked and all is ok, but I didn't like the way it flickered off on me.

The SWR on the MFJ tuner showed ok 1:2 to 1 at around 5 Watts, but as I increased power it was not a good thing :0)

So back to the drawing board.

I have a MFJ-1702C two way antenna switch so where the rig would normally go into the switch, I put the bazooka.

Then I fed one side of the switch POSITION A with a standard piece of RG-8 JUMPER CABLE to the standard pl259 input to the MFJ-949B
tuner which I normally use for the bazooka. Position two on the MFJ-949B tuner.

The other side of the switch POSITION B, I plugged in an adapter I made using a shorty piece of coax with a pl259 on one end.

The open end of the adapter I made I shorted the braid to the center conductor, then I fed it to the input of the tuner that says
"wire".

So I could switch between the double bazooka for 80 and the modified bazooka for 160.

I have the tuner and the rig grounded through the same wire (so there are no ground loops) that leads to a ground stake that is 10
feet in length just on the other side of the wall of the shack outside.

So tell me what do you think?

Hi Bob,

The Double Bazooka is a single band dipole with a unique matching system that shortens the overall length by about 10% and reportedly broadens the resonance to provide a reasonable SWR across the band. Some say that a bazooka does not need a balun ..... true, in the same way any dipole can be operated without a balun .... as long as you don't mind antenna current on the outside of the feed line shield.

I am not sure from your post whether you intend to simply convert the dipole from 75M to 160M for single band use or if you are interested in occasional 160M operation and want to keep the 75M operation. General practice in developing a multi band dipole is to feed it with open wire

line and make the dimensions 1/2 wave length on the lowest frequency of operation. In your case you want to operate on a lower frequency than the design length. You already recognize that resultant operation as a dipole will not .... as you say ... allow DX hi hi.

My recommendation is to forget using the antenna as a dipole. If you have a reasonable RF ground at the operating position the absolute best plan for 160 operation with your 80 mtr dipole is to short the feed line at the tuner end and treat the coax feed line as a single vertical antenna (centre conductor to the shield) .... the dipole will simply act as a capacity hat. Perhaps that is what you heard when someone mentioned shorting it. This will provide better performance than simply replacing the 80M dipole with a 160M dipole at the same height. If you have access to a water pipe (plumbing) try using it as your RF ground.

I worked a 160M breakfast net round table for years using a similar arrangement (dipole as a vertical with a water pipe ground) hi. With a descent RF ground such an arrangement will give you good distance contacts ... still no guarantee for DX hi .

Hi Bob,

It sounds to me from what you describe that you were trying to load up your 'shorty piece of coax' !!! First of all your antenna switch on your tuner will not be able to automatically switch you between your antenna as a dipole on 80M and vertical on 160M .... not possible. Unless i am very wrong, your antenna tuner will have a coax input (connected to your transceiver output) and a couple of coax output connectors .... eg position A & B .... for more than one coax fed unbalanced antennas. In addition you say you have a connector for a wire antenna. There are probably instructions on connecting 2 wires .... eg a balanced line or 1 wire as in a single wire.

You need to use the arrangement of a single wire. Now you can use your shorty adapter but in reverse .... the coax end goes to your feed line from the dipole ... you will have to use a female-to-female coax adapter to connect them. The other end of the shorty adapter cable .... shield and centre conductor are shorted together .... and it goes to the single wire connector.

Now when you want to use the antenna for 80M you will have to undo the coax connector on the antenna feed line from the shorty adapter .... leave the adapter connected to the wire connector .... and connect the coax feed line to either connector A or B (which ever one u normally use) and use it as a dipole on 80M .... reverse the process when you want to go on 160M again.

Also , the wire to the ground rod is very marginal as an RF ground ... it may work for static and DC safety ... but as an RF ground it is a '"0". At minimum connect a few lengths of #14 copper wire to the connector on the ground rod and run them along the ground ... around the house ... more the better ...

give it another try.

1776. RE: [SkyWires] Bazooka for 160?

Yahoo group: SkyWires
Date: 2006-09-18 01:05:24 UTC
From: AD5VJ Bob
Topic: 1770 Message: 1776

I shortened this email up to save bandwidth.

Very interesting:

I have tried two suggested methods so far please read further to see what happened:

One is the shorting method described which I will comment on a little later and this method suggested by another Ham as well:

> I have seen a number of 'compromise' setups that work
> surprisingly well. One such method uses whatever antenna you
> have for the low bands. If you take the PL259 loose on the
> antenna port, leave the center conductor sticking into the
> chassis, but slide back the 'nut' so that the shield is no
> longer connected to the chassis of the rig, you have a
> make-shift vertical. There is no need to short the center to
> the shield, but that is what some folks do (it doesn't hurt
> or help).

I used this method.
Tuned the tuner.
Went to full 200 watts output
And contacted a n7 who said he could copy me but could not make out the audio because he said he had 20 over 9 static crashes.

Then I tried the Shorting method:

It seems to tune ok with this method at low power, but if I try more than about 12W output after tuning it, the rig abruptly turns
off in such a way that I dont want to do that anymore.

I checked and all is ok, but I didn't like the way it flickered off on me.

The SWR on the MFJ tuner showed ok 1:2 to 1 at around 5 Watts, but as I increased power it was not a good thing :0)

So back to the drawing board.

I have a MFJ-1702C two way antenna switch so where the rig would normally go into the switch, I put the bazooka.

Then I fed one side of the switch POSITION A with a standard piece of RG-8 JUMPER CABLE to the standard pl259 input to the MFJ-949B
tuner which I normally use for the bazooka. Position two on the MFJ-949B tuner.

The other side of the switch POSITION B, I plugged in an adapter I made using a shorty piece of coax with a pl259 on one end.

The open end of the adapter I made I shorted the braid to the center conductor, then I fed it to the input of the tuner that says
"wire".

So I could switch between the double bazooka for 80 and the modified bazooka for 160.

I have the tuner and the rig grounded through the same wire (so there are no ground loops) that leads to a ground stake that is 10
feet in length just on the other side of the wall of the shack outside.

So what do you think?

Ideas please?

Hi Bob,

It sounds to me from what you describe that you were trying to load up your 'shorty piece of coax' !!! First of all your antenna
switch on your tuner will not be able to automatically switch you between your antenna as a dipole on 80M and vertical on 160M ....
not possible. Unless i am very wrong, your antenna tuner will have a coax input (connected to your transceiver output) and a
couple of coax output connectors .... eg position A & B .... for more than one coax fed unbalanced antennas. In addition you say
you have a connector for a wire antenna. There are probably instructions on connecting 2 wires .... eg a balanced line or 1 wire as
in a single wire.

You need to use the arrangement of a single wire. Now you can use your shorty adapter but in reverse .... the coax end goes to your
feed line from the dipole ... you will have to use a female-to-female coax adapter to connect them. The other end of the shorty
adapter cable .... shield and centre conductor are shorted together .... and it goes to the single wire connector.

Now when you want to use the antenna for 80M you will have to undo the coax connector on the antenna feed line from the shorty
adapter .... leave the adapter connected to the wire connector .... and connect the coax feed line to either connector A or B (which
ever one u normally use) and use it as a dipole on 80M .... reverse the process when you want to go on 160M again.

Also , the wire to the ground rod is very marginal as an RF ground ... it may work for static and DC safety ... but as an RF ground

it is a '"0". At minimum connect a few lengths of #14 copper wire to the connector on the ground rod and run them along the ground
... around the house ... more the better ...

give it another try.

Jim, VE3CI

1780. Bazooka On 160

Yahoo group: SkyWires

Bob,

I doubt that you stumped anyone on the Topband Reflector. Unfortunately the Topband Reflector is home to some of the snobbiest elitist's on any e-list in amateur radio and probably didn't want to waste their time on your query.

There are a couple of different design methods for a bazooka antenna and they are all for single band use only, no efficient harmonic operation possible. You could short the shack end of the coaxial feedline and feed the antenna as a current fed tee vertical but it will be poor for local or regional night time work because of the low take off angle and lack of ground radial counterpoise system.

For 160 meter local/regional rag chewing I would suggest an end fed 3/8's wave inverted L made out of #14 stranded house wire to the single wire binding post of your antenna tuner. Using 1900 kc as a target frequency the formula for a 3/8's wave antenna is 351 versus 468 for a half wave. So 351 divided by 1900 kc is 184.7 feet. I suggest a 3/8's wave length antenna as it get's the highest current point on the antenna outside in the air instead of inside right at your antenna tuner, so less RFI potential. Also a wire longer than a 1/2 wave has a higher radiation resistance and therefore is more efficient and helps to counteract losses in the ground from a poor ground radial counterpoise.

The inverted L configuration will give you high angle horizontal signal on the horizontal flat top for local and regional rag chewing and a low angle vertical signal for DX out to 1000-1500 miles. Make the vertical section as long as possible (30-60 ft) and you will be very surprised at how well the antenna works without a bunch of counterpoise radial wires on the ground. You can get by with no ground radials but I would suggest one 123 foot one for the antenna to push against so to speak.

I have four 160 meter antenna designs published on the WWW at www.kn4lf.com . Surf about half way down the site for the links.

Bazooka for 160?
Posted by: "AD5VJ Bob" rtnmi@... rtnmi
Sun Sep 17, 2006 12:50 pm (PST)
Well I sent this to TopBand Reflector first but no one has responded so I guess I stumped

'em.

Hello everyone:

I am in a space limited environment and already have a double bazooka tuned for 80 meters that works fine on 80 meters. I also have
a MFJ-949B Tuner and a manual antenna switch. Rig is an IC-775.

I have two antennas already going to the MFJ the double bazooka and a TitanDX Vertical. Therefore both PL-259 connectors are being
used.

I do have a random wire input to the tuner and a balanced wire input that are open at this point.

Does anyone know of a way I can use the Double Bazooka tuned for 80 meters (or something) at least for stateside work on 160.

I realize that DX would be out of the question without, A LOT OF HEIGHT, a Vertical, Loop or Beverage, but those are not options for
me at this point.

My only chance at this point is to somehow use the Bazooka for local calls.

Someone somewhere had said something about shorting it but if so where and how?

73 fer nw,
Bob AD5VJ(AAR6VM)

Hi Bob,
Sorry I didn't have time to get back to you . I was going to suggest taking the coax shield loose and just using the center conductor but someone beat me to it . All I can say is stick to what works .

Well now we're having fun.

1823.027 cw

Just worked two stations on Top Band.
K0VA and

Well make that three (anyway) to busy to write gotta see whets up here that's been waiting for me :0)

Thanks fellas for all your help and experience. Now we can get with it so to speak.

1784. 450 or 600 ohm feedline?

Yahoo group: SkyWires
Date: 2006-09-19 15:44:15 UTC
From: Christopher Zeman
Topic: 1784 Message: 1784

I am going to build and install a full wave 40 meter loop with homebrew ladder line. Would I be better off with 450 or 600 ohm ladder line? I've read a great deal of information online on the topic, but what do you guys prefer and why?

Chris

The best think to do (IMHO) is to make a ladder line yourself, from the same wire as the loop. Less than 4 inch between the two feeders. This will be about 600 Ohm and gives you less losses.

"...the same wire as the loop." That is exactly what I was thinking, Hans. :)

Do you think 18 guage insulated wire would be sufficient, or should I get some 12 guage. The reason I ask is that I have a spool of 18 guage sitting here. My thoughts are that I should go for at least 14 guage, but I might be wrong. :)

Additional information: between 3 and 4 inches between the two feeders
will give you about 600 Ohm.

Hello Chris,

Unfortunately I am not very familiar with the diameter of 12, 14 or 18 gauge. However I found an interesting table on http://en.wikipedia.org/wiki/American_wire_gauge

For my antennas I use 2,5mm2 insulated 7x7 stranded copper wire. This is 10 AWG.

I would use at least 14 AWG for a loop.

I'm just about finished building ladder line using cut up plastic coat hangers for the insulators. As soon as I finish, I'll post an article, complete with pictures, to the file area on here. The main problem I had, using covered #14 wire from Home Depot, was how to stick the plastic spacers to the wire covering. Stay tuned.

Hey Dave, BTW, if you go the wire-wrapping route, a fence tool from a farm and supply type store will make short work of that process! They look sorta like strange pliers, and a hammer combonation. They include a partially effective wire cutter, hammer, and grip the wire very well so you can manipulate it, including to quickly twist it about itself securely. (Take a little practice.)

I have never heard a more proper name for this tool. Simply called a fence tool. Any farmer with wire fencing likely knows what to call this, and has one, or something similar that is availble in your area.

It is a basic tool for working with wire fence, and the physics of that challenge can't differ area to area, so I'd expect similar tools evolved in each community.

Dave, I look forward to reading your future posting/report.

Here is one method I read about somewhere....

They made holes in the ends of their 'bones' (the insulator rods had somewhat larger ends than the rest, so they looked a little bit like a cartoon doggie bone). Then they threaded the wire through holes they had drilled in the wider ends of the insulator rods. Once they had sufficient number for their spacing they went back with small lengths of wire and tied the bones into place.

The wire looked a little like an unside down U with enough extra wire left over at each end of the small loop to wrap around the antenna wire/feed line wire. Once these were wraped snuggly on both sides of the bones, the insulator remained in place. Or so the story goes. I haven't tried it myself.

One could also complete the above by then twisting the two ends of the U-wire to one another.

They were using bare wire, so it is possible they finished off the twists with a bit of solder. That'd help keep the bones from slipping in the wind, up to a point.

For specific spacings and the resulting Ohms, I'm certain the "ARRL Antenna Book" has that formula in there somewhere. I'm not at home and I don't have a copy with me, so I can't tell you where. It's pretty basic formula. "Fill in the blanks" and hit enter!

You just need to know your wire dimensions and spacing (and dielectric material, of course, which in this case is air).

If you are going to use a transmatch, it won't make that much difference anyway, so long as your are in the ballpark. I seem to recall one 600-Ohm combination resulting from # 12 bare wire at a 6-inch spacing. I could be wrong however. There's no telling where that memory is bubbling up from! Hehehe...

Thanks for keeping us posted on your progress!

> VE1VQ

Hey Dave, BTW, if you go the wire-wrapping route, a fence tool from a
farm and supply type store will make short work of that process! They
look sorta like strange pliers, and a hammer combonation. They include
a partially effective wire cutter, hammer, and grip the wire very well
so you can manipulate it, including to quickly twist it about itself
securely. (Take a little practice.)

I have never heard a more proper name for this tool. Simply called a
fence tool. Any farmer with wire fencing likely knows what to call
this, and has one, or something similar that is availble in your area.

It is a basic tool for working with wire fence, and the physics of
that challenge can't differ area to area, so I'd expect similar tools
evolved in each community.

1795. Kite fest and DB9 help

Yahoo group: SkyWires
Date: 2006-09-22 04:42:05 UTC
From: icra@galaxynet.com
Topic: 1795 Message: 1795

Well....my planned ops at the kite fest this weekend is getting a little bigger than I had planned.....

Forecast at this time is not looking as good as I had hopped for....about 70F and mostly sunny.....not a good sign for kite flying winds around here...

If the wind is good, planning on 2 double extended zepp antennas supported by kites and 1 5 band vert modified to also cover the WARC bands. If winds are not very good, should be able to have a random long wire and the vert.

Rigs known to be available both days are a Kenwood 440sat and Icom IC-735.

Bands should be 20 and 15 for SSB and 30 for digital modes (if I can get this interface soldered up and working right tonight). May try 10, 12, and maybe 40 for SSB.

Known call will be N7OKL. Other calls may also be used....all depends who shows up that has expressed interest. All CQ calls will include Whidbey kite fest.

Now....any one have, or know of a site that has the pin outs for the DB-9 serial port? Thought I had it, but can not find it.....

That link for the null modem is helpful, but a little confusing. For clarity on RS-232 with a DB9:
1) Carrier Detect
2) Receive Data
3) Transmit Data
4) Data Terminal Ready
5) Ground
6) Data Communications Equipment Ready
7) Request To Send
8) Clear To Send
9) Ring Indicator

(http://www.zytrax.com/tech/layer_1/cables/tech_rs232.htm)

Hi Paul:

I was just reading about the K9AY loop antenna.

You might consider one of those sounds like you have a perfect setup and the wire ect to put one together.

From what I am reading they work better than beverages in many cases.

1801. Whidbey kite fest....aaaarrrrrrrrrgggggggggg

Yahoo group: SkyWires
Date: 2006-09-24 04:09:08 UTC
From: icra@galaxynet.com
Topic: 1801 Message: 1801

Well.....Murphy sure had his way with me......

2 hours late leaving due to flat tire.....

No parking near where I was to set up....had to man pack every thing in.......

No help to set up.........finally got the table, rigs, gen, ect set up.....forgot some power cables, soldering iron and a couple other items....now about 2000GMT......

No wind to speak of.....gave up trying to get any wire up with kites......now about 2200GMT

Got the vertical set up....but forgot some parts, so no radials or ground......About 2230GMT......lets see if it will at least tune up........tuner got it to a flat 1:1 on 20...well, some thing is better than nothing....lets see if I can make some contacts.....

Several contacts made (some with repeats....but still got 59 reports...go figure) in Texas, Minnesota, and good old FLA....no CA and that should be easy from here....

Only on for about an hour.....not much air time, but lots of interest from visitors and kite fliers.....several QSTs handed out as well as cards on the local club.....at least some PR.....

Forecast for Sun looks even worse for wind....morning fog and N winds of 5-10 at best in the afternoon......will start right off fixing stuff that went wrong today and just throwing up an inverted V for 30mtr PSK31 and focus on 20 and 15 SSB...

Mel
N7OKL

1802. Whidbey kite fest...last day....planned freqs

Yahoo group: SkyWires
Date: 2006-09-24 15:22:19 UTC
From: icra@galaxynet.com
Topic: 1802 Message: 1802

Well.....last day.....

Look for me on the following freqs:

30mtrs.......10.142 PSK31

20mtrs.......14.285........first half of the hour

15mtrs........21.355.......last half of the hour

With the lack of wind yesterday, and the poor forecast for today, expect to be on the vert for SSB and an inverted V for PSK31.

If we get some wind (HA), will try to fly 1 wire doublet that can be bounced around the bands......do not hold your breath on it.......wish they could hold this thing in about May or July when we have a better chance of good wind

And, running late...as usual.....should be on the air about 1700-1730GMT

From: Robert Mozulay
Topic: 424 Message: 1804

Hi Paul,

Yes, I use my 80 meter loop on the upper half of 160m.
Its height is about the same as yours.

I cannot tune the loop on the lower half of 160m---I assume
the impedance looking into the transmission line towards the loop on the lower half of 160m
is out of the range of my antenna tuner (Ten Tec L tuner, roller inductor type).

73s,
Bob/WB2UFE

1805. What can go inside the loop

Yahoo group: SkyWires
Date: 2006-09-27 06:47:43 UTC
From: Paul
Topic: 1805 Message: 1805

I'm considering putting up four 40 foot metal masts, guyed with dacron, to support a 40M loop. I don't plan to cut it to a particular length because I don't have a lot of options for mast placement. The loop will probably be about 200 feet.

Underneath the loop, I guess about 4 feet below, I plan to run a 40M windom diagonal, under that, maybe another 4 feet, on the other diagonalon the opposite diagonal, I thought I'd string an extended 20M dipole.

So looking down from the top, it looks like a box with an X in it - except the box and each line of the X are at different heights.

Finally, somewhere inside the loop, I thought I'd put up a 20 foot mast with a Gap Titan on top if it. That would put the top of the titan at 45 feet.

The loop would extend over the house and back yard. the Titan's mast would be attached to the back end of the house so would be about 15 to 20 feet from the loop edges. Not sure about it's proximity to the dipoles.

If I only use one antenna at a time, are there any adverse issues about the close proximity to the various antennas.

If the above seems to ambitious, I could go with just the loop and interior mast/Vertical. Perhaps they will give me all the options I need.

But once I put the masts up, they are pretty much up. So I'm trying to get as much use out of them as I can. Maybe I can just install pullies and haul lines for any future wire.

What do you think?
Thank you for any advice.
73,
Paul

PS: The power company is building a new substation about a quarter mile away.

PS: The power company is building a new substation about a quarter mile away..___

.

Hi Paul,

I was waiting for anyone else to take your question , but I will give you my opinion . It sounds like your loop will be bigger than a full wave for 40 meters. Keep in mind that you can run Dacron or rope etc.. from each support to hang / suspend a smaller loop nearer the middle of the supports .
Almost all of electronics is a compromise is some way or another . By putting other antennas in the loop it will have some affects on pattern , impedance, gain, etc... But I would not be too concerned . If it works use it.
If you want to test the actual effects , put up the loop antenna and then introduce the other antennas one at a time . And you will be able to measure/see the practical implications . I very seriously doubt that the negatives will out way the positives .
Pulleys for future wires is always a good idea .
As far as the power co. substation a 1/4 mile away keep in mind that they are limited to their rf emissions by FCC rules . The ARRL helps members with such matters . My friend W4NTI had problems with his local power Co. that they refused to address. His complaint was rectified !
SEE Below-
Good Luck es 73 Ace - WH2T

January 30, 2002

Mr. Elmer B. Harris, CEO
Alabama Power Company, Inc.
P.O. Box 2641
Birmingham, AL 35291

Dear Mr. Harris:

The Federal Communications Commission has received complaints that equipment operated by your company may be causing harmful radio interference to operators in the Amateur Radio Service. The complainant is:

Daniel L. Jeswald, W4NTI
89 Wildman Road
Anniston, AL 36201

The FCC has the responsibility to require that utility companies rectify such problems within a reasonable time if the interference is caused by faulty power utility equipment. Under FCC rules, most power-line and related equipment is classified as an "incidental radiator." This term is used to describe equipment that does not intentionally generate any radio-frequency energy, but that may create such energy as an incidental part of its intended operation.

To help you better understand your responsibilities under FCC rules, here are the most important rules relating to radio and television interference from incidental radiators:

Title 47, CFR Section 15.5 General conditions of operation.

(b) Operation of an intentional, unintentional, or incidental radiator is subject to the conditions that no harmful interference is caused and that interference must be accepted that may be caused by the operation of an authorized radio station, by another intentional or unintentional radiator, by industrial, scientific and medical (ISM) equipment, or by an

incidental radiator.

(c) The operator of the radio frequency device shall be required to cease operating the device upon notification by a Commission representative that the device is causing harmful interference. Operation shall not resume until the condition causing the harmful interference has been corrected.

Title 47, CFR Section 15.13 Incidental radiators:

Manufacturers of these devices shall employ good engineering practices to minimize the risk of harmful interference.

Title 47, CFR Section 15.15 General technical requirements.

(c) Parties responsible for equipment compliance should note that the limits specified in this part will not prevent harmful interference under all circumstances. Since the operators of Part 15 devices are required to cease operation should harmful interference occur to authorized users of the radio frequency spectrum, the parties responsible for equipment compliance are encouraged to employ the minimum field strength necessary for communications, to provide greater attenuation of unwanted emissions than required by these regulations, and to advise the user as to how to resolve harmful interference problems (for example, see Sec. 15.105(b)).

The complainants have attempted unsuccessfully to work through your usual complaint resolution process and as a result the matter has been referred to our office. The FCC prefers that those responsible for the proper operation of power lines assume their responsibilities fairly. This means that your utility company should locate the source of any interference caused by its equipment and make necessary corrections within a reasonable time.

While the FCC has confidence that most utility companies are able to resolve these issues voluntarily, the FCC wants to make your office aware that this unresolved problem may be a violation of FCC rules and could result in a monetary forfeiture for each occurrence. At this stage, the FCC encourages the parties to resolve this problem without FCC intervention, but if necessary to facilitate resolution, the FCC may investigate possible rules violations and address appropriate remedies.

The American Radio Relay League, a national organization of Amateur Radio operators, may be able to offer help and guidance about radio interference that involves Amateur Radio operators.

American Radio Relay League
Radio Frequency Interference Desk
225 Main Street
Newington, CT 06111
860-594-0200
Email: rfi@...

Please advise the complainant within 30 days of what steps your utility company is taking to correct this reported interference problem. The FCC expects that most cases can be resolved within 90 days of the time they are first reported to the utility company. If you are unable to resolve this within 90 days, please advise this office about the nature of the problem, the steps you are taking to resolve it and the estimated time in which those steps can be accomplished.

If you have any questions about this matter, please contact:

W. Riley Hollingsworth
Special Counsel
Enforcement Bureau, FCC

Thank you for your cooperation.

Sincerely,

Jack Forsythe, Chief
Consumer Information Network Division
Consumer Information Bureau

1807. is this possible? an all band, tuned dipole??

Yahoo group: SkyWires
Date: 2006-09-30 03:34:56 UTC
From: chasm@texas.net
Topic: 1784 Message: 1807

Is it possible to put up a dipole of about 120', with ladder line coming from the centerpoint, and it be a resonant wire from 3.5 to 30mhz, no more than 2:1 swr or less? iow, an all band or broadband, tuned wire capable of a legal limit input??

we have a fellow on the net running a 170' wire with a center at ~60ft and the ends at >20'. This is the best signal in the state. but it requires 100ft of ladderline and a tuner. I would like to get it shorter as in a max of 115' and have a matching network in the center which would handle a kilowatt and be flat across the HF bands. continuous, all band coverage and no, not a folded dipole. but it would have the characteristics of a BWD-90.

I want to put this up flat at about 50' here in Houston.

thanks/chas

Hi there!

Sure is possible as I've been doing it since I was a Novice but you will need a good antenna tuner...

I use 130 feet feed with home made ladder line spaced 3 or so inches... I use an old Johnson Match box for 80 - 10 and home made tuners for 6 and two meters... works quite well and I seldom see an SWR greater than 1.5 to 1... generally it is so low that my old Knight kit SWR meters can't even read it...

But don't get the idea that because you might have a low SWR that things are working hunky dore... sometimes it isn't that easy...

Try it out as I am sure once you get it set up you will be more than happy with it...

>
>Sure is possible as I've been doing it since I was a Novice but you will need
>a good antenna tuner...

I don't suppose I clarified the specific points

1. about 115' and a single wire
2. balanced line/antenna
3. NOT require a tuner
4. essentially imitate a closed loop dipole as in BWD-90/T2DF
5. swr on all bands to be less than 2:1, capable of 500W
6. ALL HF bands 3-28 mcy at least, tuner above that perhaps.

is it possible to do this ?

The reason for this antenna

1. light weight
2. suspension at 50' flat topped, survive 90mph
3. capable of ALE/HF Digital modes -- iow, NO TUNING

apparently, it will need a "matching network" whatever that is, to eliminate
the tuner..

there are at least a couple of dipoles which will do what I want but they are
heavy, not enough wire in the sky, etc. one example is the Cobra, another is
the ubiquitous T2FD/Barker and Williamson embassy antenna which we used to see
on the roofs of most Texas DPS Regional HQ.

thanks

When you say 3-28 MHz, and "continuous," you are implying this is not a ham-band antenna, you want it to work on frequencies in between the ham bands too. Is that right?

If so, the simplest way to do it is with a dummy load. But then of course you won't be getting out! At least not very well.

For a tuner-less antenna, you could try designs like the T2FD (B&W etc.) which use resistors that dissipate varying amounts of power, and keep the SWR reasonably low over a wide frequency range. Just be aware that your efficiency won't be top notch. Some swear by them, others swear at them. The government seems to like them, probably because they don't require tuning, and their frequencies aren't harmonically related like the ham bands are.

If all you need are ham bands, there are alternatives. Ham bands are easier because symmetrical dipoles automagically work on odd harmonics too.

> 3. capable of ALE/HF Digital modes -- iow, NO TUNING

While partly true, you don't need an HF antenna to be matched or tuned when receiving (and in fact some antenna tuners bypass when not transmitting), you only need it matched for transmitting; and you can get auto tuners with memory that will match within milliseconds after starting transmitting, which works pretty well for ALE. Don't count it out.

> apparently, it will need a "matching network" whatever that is, to
> eliminate
> the tuner..

They are the same thing. (Though some might argue that one is used at the antenna feed point and the other at the rig end of your feedline.)

It's just that we've gotten accustomed to those antenna auto-tuners, that we forget it used to be commonplace to use a fixed-tuned network that would match an antenna (that wasn't already a good match) to a feedline. Now we let the auto-tuner take care of it. They do the same thing, except one is manually tuned (or fixed tuned), the other is automatic.

Yes, a dipole of any length fed by ladder line of any length can be fed power at any frequency between 3.5 and 30 Mhz and be matched to the transmitter with an appropriate antenna tuner. However, you will be operating on set Amateur frequencies and certain combinations produce favorable impedances on most Amateur bands .... but not all. If you Google Cebik you will find he has run some computer simulations of different combinations that work well on the Amateur bands.

This is a very effective all band antenna .... but don't confuse it with a broadband antenna ... it is not broadband ... as you change frequencies the impedance at the radio end of the feed line changes dramatically and a tuner must be used to match it to the radio input.

>we have a fellow on the net running a 170' wire with a center at ~60ft and the
>ends at >20'. This is the best signal in the state. but it requires 100ft
>of ladderline and a tuner.

As you describe this fellow's antenna it is an example of a tuned dipole antenna system.

>I would like to get it shorter as in a max of 115'
>and have a matching network in the center which would handle a kilowatt and be
>flat across the HF bands. continuous, all band coverage and no, not a folded
>dipole. but it would have the characteristics of a BWD-90.

Here, it sounds like you are talking about a different antenna system .... with a matching system at the center of the antenna. I am not sure what you mean by a matching system .... do you mean an automatic antenna tuner? What you are describing sounds more like a Terminated Folded Dipole (I know you don't want to hear 'folded dipole') ..... Cebik who I mentioned above has also modeled this antenna and he has an article on the internet on the subject. All of these "broadband" antennas are forms of terminated travelling wave antennas. The matching network you mention is simply a resistor (carbon ... non wire-wound) fed by lengths of wire in various configurations and often with a RF transformer to match the input impedance of the radio to the value of the resistor. In these antennas a large portion of the RF power is consumed in heat by the resistor and some in the travelling wave feed wire (which is radiated). If you want to run high power you need a resistor that can absorb the high power.

Years ago there was a manufacturer of a magic dipole that could be any length and produced a 1:1 SWR across all the HF bands. They provided a sealed "matching" network that you simply placed at the center of your dipole and fed it with coax cable. QST did an expose of the device (by breaking it open) and found it simply contained a 50 ohm resistor ..... it was a dummy load with connectors for wire. It radiated, but most of the energy was absorbed by the resistor.

True travelling wave antennas although terminated in a resistor are not as inefficient as the hoax example above .... but to be sure at least 50% of the power is absorbed by heat. To be effective travelling wave antennas are usually quite long. The advantage of these antennas is that they are quite broad banded, they can be fed by coax, and some of them exhibit gain due to their radiation pattern ...

Some of the configurations of the travelling wave antenna are the (folded) dipole version as in the BW, Inverted Vee with each end terminated to ground (see the Ten Tec site), The Rhombic .... a horizontal loop like antenna .... there are other types but used primarily for reception rather than transmitting .... such as the Beverage and K9AY loop.

I don't mean to be obstinate, but these broadband antennas are not 'tuned' .... The reason the antenna is 'terminated' in a fixed carbon resistor is to avoid resonance and the need for tuning. The RF travels along the wire to the terminating resistor and creates travelling RF waves (thus they are called travelling wave antennas). The B&W antenna is the only travelling wave antenna commercially available in a dipole configuration. If you are interested in building such an antenna I recommend looking at the Cebik site online .... he has modeled all the wire dimensions and the values of terminating resistor and impedance of the coupling transformer.

Hi Chas,

The simple answer is "no".

While you can receive (RX) wide-band (in this case 30 through 3.5 MHz) without too much trouble, you can not do the same while transmitting (TX) into anything other than a dummy load.

To expand on the thought....

First, even on RX you will find better performance from a tuned antenna. By tuned I mean some type of impedance matching network is being used in between the antenna and the transceiver (XCVR).

As another poster noted, this impedance matching network can take a number of different forms. A transmatch (antenna tuner) is most common for those occasions when band-hoping is desired.

If you are working a fixed frequency actually cutting or lengthening one or more of the antenna's elements (wires/pipes/etc) is common.

Other common impedance matches are accomplished by adding fixed or variable coils and capacitors at the antenna feed point.

But they all perform the same function: they eliminate reactance (which is resistance to alternating current, and either capacitive (electrostatic) or inductive (magnetic)), and then match the resulting purely resistive load value to the XCVR's output.

Since on RX you are not TX-ing (by definition) you can not damage your radio by listening out-of-band, so to speak. You may not hear as many faint and/or distant stations without tuning your RX-antenna, but you won't damage anything either. (Barring lightning or other giant sudden inputs.)

This is not always true when transmitting.

I can't explain the physics of reflective waves and the resulting heat build-up inside the transmitter, but I can tell you what you likely already know. If you transmit into a significant impedance miss-match you can damage your transmitter.

I do know (read "Reflections II" by Maxwell w2du) that poor swr isn't what damages the transmitter, it is the internal reaction of the transmitter (inside the transmitter, separate from the reflected wave that causes the poor swr) that causes the finals to blow. A fine point however when your XCVR is smoking on your desk!

It's like saying it isn't the engine that caused the drive shaft to twist apart, but that the drive shaft wasn't able to withstand that much torche, that caused it to twist apart. Either way, your done!

So, to answer your original question, you will need some type of impedance matching network, unless you use a dummy load.

As you know, a dummy load presents an essentially zero reactance (j0 Ohms) load to a wide range of input frequencies. In other words, a dummy load is close to a pure resistance, at the transmitters output impedance (typically 50-Ohms, j0-Ohms). But it doesn't radiate the RF very well, so it makes a poor antenna. Strike that from the list!

What remains is the host of transmitting antennas.

I don't recall if you discussed the height at which you plan to mount your antenna. If it is less than 25% of a full wavelength (WL), it is a NVIS antenna (as most of us have, at least on the longer bands).

For anyone new reading this, that formula is:

Height =~ 300 / MHz * 3.3 = Feet * 0.25

where, "Feet" is the full length of one wave at that frequency. To find x% multiply by the needed %. In my example I wanted to find how long 1/4 of the full wavelength was so I multiplied by 0.25 (the same as dividing by 4).

For example (in the phone portions):

20-Meters: 300 / 14.225 MHz * 3.3 * 0.25 = 16.9 feet;

40-Meters: 300 / 7.225 MHz * 3.3 * 0.25 = 34.3 feet;

80-Meters: 300 / 3.85 MHz * 3.3 * 0.25 = 64.3 feet;

The reason I bring this up is that you will be able to use two antennas at right angles to one another at these lower heights and not have much detrimental affects due to height. Another way of saying that, is there will be so much ground-clutter at these lower heights that you can cross a couple antennas without really adding any noticeable negative affects, hehehe....

You may find crossing two dipoles in your lot allows you to obtain a better match for any given frequency. Something to consider anyway.

I'd expect a transmatch of one type or another would be the best impedance matching network to use. It is the most flexible, meaning it'll match a greater range of possible impedance differences between your antenna system and the XCVR.

Most popular for manual transmatches is the T-network (C-L-C layout) but the pi-network also has a wide matching range, and some people really like those. I've only used the C-L-C design myself, so I have no opinion to offer on the pi.

Or you can buy an auto-tuner. You can also find transmatches designed specifically for use with balanced-wire feed lines too. (Open wire/ parallel wire/ balanced wire/ ladder line/ twin-lead/ window wire/ they are all the same basic type of transmission line.)

You can also achieve an impedance match by altering the length of your transmission line. This is the most bulky to use in my opinion, but it'll work. One thing many people do is keep one or more alternate lengths of transmission line around to switch in/out before entering the transmatch (either coax or ladder line may be used, but coax is easier to work with in terms of being able to pile it up anywhere - ladder line requires separation between the various bits of line to allow them to remain balanced, which is why they have such low loss (no closer to anything than one width of the space between the wires, and several such widths is even better)).

Speaking of transmission line.... so long as you use open wire of some kind your transmission line loss will likely be so low you won't have to worry about it at all. Open wire line is very nice for both long runs or operating at high swr.

With high swr it isn't that the RF isn't getting out your antenna. It is. The RF will reflect, re-reflect, and re-re-reflect ad nauseam until it gets out the antenna and into the atmosphere. That isn't the problem. The problem with high swr (other than potential transmitter damage) is the loss inside the transmission line. Since open wire has very little loss, this isn't a concern. If however, you are using coax this needs to be considered. It may be a problem or not, but you need to put a pencil to it anyway.

Imagine the RF bouncing between the antenna and the transmitter, back-and-forth, back-and-forth. If only 0.001% of RF is lost each trip, who cares? But if 5% or 10% is lost each trip you can see how that can much more quickly add up to a large loss after just a few trips back-and-forth. That is the loss issue with high swr and lossy transmission line. High swr means many bounces back-and-forth and lossy transmission line means a lot of RF is converted into heat along the way and is no longer available to radiate as the RF energy we desire.

Short runs (under 50-feet) and very low swr (under 1.5:1) shouldn't normally cause too much RF loss. As you begin to get over 2:1 swr or over 100-feet long runs of coax you need to be increasingly concerned about the losses.

So there you go!

Hehehehhe, we all always have an opinion, and leave it up to you to decide!

Have fun playing with your antenna system!

Lots of excellent advice in Erik (N0EW)'s message.

But I do disagree with some points:

> With high swr it isn't that the RF isn't getting out your antenna. It
> is. The RF will reflect, re-reflect, and re-re-reflect ad nauseam
> until it gets out the antenna and into the atmosphere. That isn't the
> problem. The problem with high swr (other than potential transmitter
> damage) is the loss inside the transmission line.

Well ... that isn't entirely true. The power initially reaches the antenna, but it reflects back and probably gets either absorbed back into the transmitter, or is purely reactive power and doesn't really go anywhere (though some also gets re-reflected back). It is quite true that there is more loss in the feedline. But it isn't true that all of the remaining power eventually gets radiated.

Simply because of the fact that there is an impedance mismatch (from the impedance that the transmitter wants to see), means not all of the available power gets into the antenna from which it can radiate.

An SWR of close to infinity will be radiating very little power. Some of the rest heats the feedline, but by no means is it all of the rest.

Regards,
Andy

thanks for your input.

ok, now if I am going to be using an autotuner with an unbalanced antenna or mess of antennas, it seems to me that it needs to go between the amplifier and the antenna? or does the wattmeter/SWR need to go bettween the amp and the tuner? I am using an 811 (Ameritron) and mostly on 75 and 40 meters (MARS).

the primary antenna is my Alfadelta DX-CC at 40' with 25' ends. the length has been tuned to 4.1mcy where flat SWR is very narrow. for 40m, the harmonic seems to be about the 7.2s with equally flat SWR.

so, what kind of AT do I want which will tolerate about 500W ???
and, what is the proper sequence coming out of the amp for the AT and Wattmeter?

it is amazing how much more I learn from the elmers here than I can from all the ARRL library!! and I first started my licensing when I was about 10yo in the early 1950s hi hi

thanks

Well Andy... we'll just have to agree to disagree. This a commonly misunderstood topic. I suggest "Reflections II" by W. Maxwell w2du. Very informative, although it requires more than one reading to 'get it' (that was my experience, and I don't claim to remember all of it yet! I need yet another reading!!!).

More below for those interested....

I may not have given reactance a full measure of discussion. If it isn't eliminated from the antenna system, it will create an 'eddy' in the current, so to speak. Reactive power is lost to us as effective radiating RF. It gets caught up in a repetitive loop, doing no useful work for us.

But all power not lost as heat does radiate from the antenna, unless caught in a reactance loop. Conservation of energy tells us all energy does something. It must. RF becomes heat. RF is caught in a reactive loop. Or.... what is left? I can only think of radiation.

Reflected power is re-reflected from the XCVR (or transmatch, if used). No power is re-absorbed by the transmitter. That isn't why a transmitter is damaged under high swr, but it is the common view. It is the transmitter's reaction to being unable to properly load into the antenna system that in turn causes the damage to the transmitter. It is a subtle, but true, difference.

I will admit that the subtle difference doesn't hold much meaning to a person looking at a smoking XCVR that no longer works!

I can't fully verbalize it. Read "Reflections II" or some of the electrical engineers reports (IEE?) that I can't possibly recall where I came across.

> Simply because of the fact that there is an impedance mismatch (from the
> impedance that the transmitter wants to see), means not all of the available
> power gets into the antenna from which it can radiate.

In a word: yes.

Anytime an impedance mismatch is present not all power can be transmitted from one point to the next. What we amateurs think of as "impedance" can be thought of as a measure of the effectiveness of matching a source to a load. Or we can think of it as how much of the RF will get by the terminal, and how much is lost in the crossing (I'm watching a herd crossing the river, and seeing some lost to croc's, hehehe!)

Any time the impedance between the source and the load differs, we suffer an inefficiency in transmitting power across that junction, or node.

Now a load need not be the final destination. There are impedance changes at many points between the transmitter and the antenna. In a common amateur radio station's set up, many of us have a XCVR -> Coax -> Transmatch -> Feedline -> Antenna. There may be a balun in there too, which adds another component and length of feedline. At each junction (a point of transmission across the different materials) there is possibly (likely actually) a mismatch in impedance. It may a large or small mismatch in impedance.

We often use a transmatch to take all these lump-sum impedance changes as seen at the output of the transmatch (antenna tuner in common parlance) to be set equal to the transmatches input impedance, after off-setting any present reactance. The typical input impedance (from the XCVR to the transmatch) is a nominal 50-Ohms with little to zero reactance, and typical coax is a nominal 52-Ohms.

Not much difference so far. Maybe 2-Ohms, and some very small amount of reactance. These are just nominal values and may be off a little either way, so maybe they nearly offset each other (becoming a closer impedance match) or maybe they are both off in the same direction. In any event, given good materials and properly operating equipment, nearly no difference so far....

This is why the impedance change between the XCVR and transmatch's input is very small. Between the transmatches output terminal and the end-point (our (hopefully!) radiating antenna wire) there can be many difference impedance encountered.

Once the transmatch is properly adjusted, reactance is off-set (if -j 300 Ohms were presented to the transmatch, it'll inject + j 300 Ohms, leaving a net of j0 Ohms, or zero reactance (strictly speaking, it is

likely some small amount of reactance will remain, but be of quite small magnitude, so we say it is gone, because for any noticeable difference to us, it is gone)).

The remaining pure resistance difference is adjusted in such a way as when the reflected wave is re-reflected from the transmatches output terminal (no reflected wave reaches the XCVR) through the transmission line to the antenna feed point, it will now equal the antenna's impedance, and because the re-reflected wave's impedance matches the antenna's feed point impedance, the energy is absorbed by the antenna (the load) and then radiated into the atmosphere.

So while the adjustments happen simultaneously, we can construct a mental image showing a two-step process inside the transmatch. It brings the reactance to near-zero, and it alters the remaining purely resistive portion of the energy in such a way that the antenna will enjoy a well-matched impedance at it's feed point.

However, if we don't use an impedance matching network (I almost always use a transmatch if there is much of a mismatch, but there are other options), that reflected wave still re-reflects off the transmitter's output terminal. It still doesn't enter the transceiver. The XCVR is still damaged by it's own internal struggle to load into an impedance mismatched to it's designed generator's impedance (in our case the generator is the transmitted RF).

So the reflected wave becomes a re-reflected wave. Some of the energy in the second trip is again lost as heat. Some of this 2nd wave enters the antenna. Some of the 2nd wave is re-re-reflected back toward the XCVR.

As the second wave, the re-re-reflected wave, hits the XCVR, it becomes the third forward wave. This is the ad nauseam cycle. (We should remember there are additional initial forward waves being newly created as the earlier waves reflect and re-reflect. This takes place to make the issue more complex to reason out - just joking!)

So, if you isolate one instant of forward wave and watch it batter itself back-and-forth, ultimately one of three things happens to each mote of energy: (1) it is converted from RF into heat; (2) it is caught in a reactance loop and endlessly cycles back-and-forth in it's own little 'eddy' in the alternating current, doing essentially nothing; or (3) it is radiated from the antenna into the atmosphere.

I'll have to think more about the infinite swr question.... Off-hand I'd say it'd be important to know why it is infinite.

If due to reactance, then I'd say very little radiation can be expected because nearly all the energy is caught up in that repeating loop in which it does no useful work (no radiating RF). If due to a resistive mismatch, I'd expect the RF to radiate eventually because it is bouncing back and forth along the entire path. Each time some of it

will get radiated by the antenna, even if only a tiny fraction, so ultimately escape into the atmosphere. Of course, the XCVR may soon blow up. Also, we'd need to compare the tiny amount radiating to the amount lost as heat. It may be a much more efficient heater than a radiating element, so in that case, even if given a pure resistive and infinite swr, we might expect very little RF radiation. Sorta like a space heater!

Hmmmmm.... OK. I'll go with that. Infinite swr results is no measurable RF radiation, as the RF energy is either caught up in an endless reactive loop, or radiates fully as heat.

Or we blow up the XCVR and don't have to worry about those pesky motes of RF trying to trick us anymore, so there!!!

Hi Chas,

I'll stay out of this! I have a couple amps but have not yet put them
on the air. I'd expect anything rated for the amps output can go in
any position, and anything rated less than the amp needs to be between
the XCVR and the amp. But that is only an uninformed guess.

> it is amazing how much more I learn from the elmers here than I can from all

> 73/chas

OMG! Don't get me started! The ARRL causes at least as many
misunderstandings as it helps to solve. I still buy ARRL literature,
but I don't expect to actually learn anything. Just disconnected or
incomplete bits, some of which I know from experience will be wrong.
It is up to the reader to determine the truth from the distorted or
outright wrong. Tough going if you are still trying to learn that topic!

I think of all ARRL materials as just one bit of resource material.
Treat it like a research paper. Starting out you don't know what is
true. You can only hope to figure it out either by eventually learning
the topic or by finding enough thought-to-be reliable source to form a
consensus.

Good luck!
Erik n0ew

Subject: Re: [SkyWires] is this possible? an all band, tuned dipole??

ok, now if I am going to be using an autotuner with an unbalanced antenna or
mess of antennas, it seems to me that it needs to go between the amplifier and
the antenna? or does the wattmeter/SWR need to go bettween the amp and the
tuner? I am using an 811 (Ameritron) and mostly on 75 and 40 meters (MARS).

the primary antenna is my Alfadelta DX-CC at 40' with 25' ends. the length
has been tuned to 4.1mc where flat SWR is very narrow. for 40m, the harmonic
seems to be about the 7.2s with equally flat SWR.

so, what kind of AT do I want which will tolerate about 500W ???
and, what is the proper sequence coming out of the amp for the AT and
Wattmeter?

it is amazing how much more I learn from the elmers here than I can from all
the ARRL library!! and I first started my licensing when I was about 10yo in
the early 1950s hi hi

thanks

.

Hi Chas,
The antenna tuner goes between the amplifier and
the antenna . The antenna tuner should be the last item in line to the antenna .
The order should be Radio , Amp , Pwr/SWR Meter , antenna tuner .

You can get a good used antenna tuner on eBay .
A big factor is if you plan to use coax or balanced feedline !
I use a MFJ 989C and also a Murch Electronics Model UT-2000B.
The MFJ 989C will handle 1500 watts on 75/80 mtrs but only about 900 watts on 160 mtrs .

Many commercial tuners are very unbalanced on the "balanced" line
output.
Outside of the Johnson Matchbox series link coupled tuners (perfect
output balance) the only commercial tuner I know of with very good
balanced output (at least on 160 and 80M)is the Murch UT-2000B with
factory triple core balun.

FYI - Murch Info
The 2000A is 80 - 10 meters only.

The 2000B is 160 - 10 meters with a reflected power meter built in.

Based on Lew McCoy's ultimate transmatch design of the early 1970's, this tuner will tune just about anything.

Rated at a conservative 2000 watts and tunes all frequencies between 3.5 and 30 MHz, Coax or long wire.

One of the best high power tuners made. Roller inductor turns counter makes for easy re-setability.

Great for use with a G5RV, Carolina Windom or other coax fed multi-band antennas.

Here are some pricey antenna tuners

The Nye Viking MB-II Antenna tuner will handle 3KW into loads from 40 to 2000 ohms. Frequency range from 1.5 MHz to 30 MHz.

3KW capability.

Nye Viking MB-V-A Antenna Tuner Frequency Range: 1.8 to 30 MHz continuous (160 to 10 meters)*

*1.8 MHz will not tune on some antennas.

Drake MN-2000 10-80 Only NO meter 160 Coverage

Good Luck and very 73, Ace - www.WH2T.com

1821. Easy to use antenna tuner for under 500W?

Yahoo group: SkyWires
Date: 2006-10-04 19:49:41 UTC
From: icra@galaxynet.com
Topic: 1784 Message: 1821

Looking for recommended antenna tuners that cover 160-10 (including WARC bands and 60mtrs), is easy to use, and is cheap.....max power I am able to use is about 200-300W and current rigs max out under that range (too many people living too close to use higher power within RF exposure levels).

Current tuners on hand:

Kenwood AT-180....very nice, easy to use, 160-10 but no WARC or 60mtrs, poor bal output (not that I use bal line much), built in antenna switch (2 coax, 1 'bal' line and dummy load), built in SWR/power meter.....Does not match a very wide range of antennas.....really only good if it is close to begin with.....at least not for me

Heathkit SA-2040....Full legal power, matches very wide range of antennas, good bal output (from what I can tell).....but....no antenna switch....limited to 1 antenna at a time (coax or single wire or bal line if you move a shorting bar on the back) and very hard to use (for me)....never gotten it to match any thing...mostly due to operator error....going to trade it for some thing easier to use and all ham band coverage.....why I am asking for input.....

Your thoughts?

obviously this is not an auto tuner so,
when it is in its position between the amp and the antenna, with the
SWR/WATTmeter between it and the amp ---

how do you tune the Murch 2000B (the "B" just for its meter??) ?
again, I have NO interest in 160m... I am primarily into MARS freqs on 75 and
40m. using dipoles, mostly unbalanced but I do plan to put up a long (120'+)
wire at 60' flat topped with ladder line feed. will be running an antenna
switch behind the tuner with one lead into a 600W air load resistor

thanks

You can put up virtually any kind of antenna, and make it work, as long as
you feed it with an antenna couple that can handle the antenna's
characterists...

Hi Chas ,
The Murch UT-200B has a built in "Relative" Reflected power meter . You just adjust the Inductor , Input , and Output controls until you get a minimum "Relative" Reflected power reading .
You can also have and use a SWR/WATTmeter between the Murch UT-200B and the amp.

Mel,
Since you are only going to run 300 Watts max . An automatic antenna tuner might make the best choice for convenience . I know some of the guys in this group use remote automatic antenna tuners located near the antenna feedpoint ! You run coax from the station to the remote automatic antenna tuner.
I don't remember the brand name of the remote automatic antenna tuner, sorry .

Hi Everyone,
I uploaded a file to the file sharing area for our group. It's a handy chart for logging the settings on a manual antenna tuner . I added the 5 Mhz / 60 meter band on the chart .
Note : The columns marked "Transmitter" and "Antenna" can be renamed Input and Output.
Also , The columns marked "Transmitter" and "Antenna" could also be renamed Tune and Load and the chart could be used to log the setting for a HF amplifier.
73 to all, Ace - WH2T

P.S. If anyone wants I can change the columns names and eMail you the new file .

SGC's line of remote tuners. low power... 200W or so.
but you can put them on the tower base, or mount them on the mast and feed
directly into the centerpoint of a dipole.

hope this helps

I am a great Sterba fan - as you noted, I just rallied some to the
cause, and alienated others. Well, just remember, if you don't
occasionally stir up some criticism the only certain thing is, you
have attempted nothing!

This is especially useful advice to recall when standing in front of
your local club listening to complaints. No matter what you do or say,
some will like it, some will dislike it and most aren't much moved
either way. Just like art.

There have been at least two Kurt's as well. Perhaps more.

The most recent Kurt offers incomplete information which the old Kurt
would never have done. This is a sad turn of events because it was the
completeness of his answers that made his work so much of a learning
experience. He helped connect many of the dots other works left
incomplete.

He is also nicer in his tone. I was originally attracted by the Krusty
Kurt, and that he spoke bluntly. I appreciate that in our overly
Politically Correct (and vague) world.

Off to the rest of the postings....

Hello Loop Folk, This is my 1st Post. Im sure this has been asked many times before but if one desgned a large loop say for 1 wavelength of say 500khz & therefore it would operate on every harmonic so 1, 1.5, 2mhz etc & given its most useable highest frequency of 8x (because of excessive nulls & peaks in its horizontal plane would be 4mhz - Does this sound about right?

Anybody ever discussed lowering the Q of a loop by creating a caged wire similiar to the caged dipole's thus enabling perhaps a 7% bandwidth increase on at least the fundamental frequency?

I was toying with the idea of a near perfect loop. I pictured a neat clean conventional Loop Skywire with a classic square shape in a flat field but instead of wire I used nylon rope. The nylon roped loop was oversized for the funamental frequency but suspended inside this nylon square was a large number of small insulators that formed a neat circle shape that I fed with conventional wire for the actual antenn thus giving me a near perfect circle, thereby producing a cleaner omnidirectional pattern across all harmonics. Any thoughts on that crazy idea.

Fianl Question of feeding the beastie. I understand the basic impedence of a loop on its fundamental or even 1st harmonic is in the order of 125ohms. I always thought about feeding it with a parallel RG58 (52 Ohm) coax thus producing a balanced 100ohm feed or if primarily operating on a higher order harmonic then feeding it with parallel75Ohm coax for 150 Ohm balanced feed a giving Low loss balanced feed for a close match to its impedence. Does this sound Feasable to anyone else?

Thanks for reading my thoughts & questions

Hello Loop Folk, This is my 1st Post.

Snipped

Anybody ever discussed lowering the Q of a loop by creating a caged
wire similiar to the caged dipole's thus enabling perhaps a 7%
bandwidth increase on at least the fundamental frequency?

That idea sounds very similar to a rhombic antenna. I made my full wave horizontal loop using a single strand of bare, solid, copper, 8AWG wire. It covers 3.75 - 4 Mhz with a 2:1 or less SWR without a tuner.

Fianl Question of feeding the beastie. I understand the basic
impedence of a loop on its fundamental or even 1st harmonic is in the
order of 125 ohms. I always thought about feeding it with a parallel
RG58 (52 Ohm) coax thus producing a balanced 100 ohm Low loss
balanced feed for a close match to its impedence. Does this sound
Feasable to anyone else?

I have had the same idea. It should work well.

Give it a try. First on paper, afterwards on small scale and thereafter
in your garden.

The impedance of the (balanced, parallel, open) feederline will vary
because of the distance between the two feeders of the line.

A distance of about 3 to 4 inch between the feeders will give you about
600 Ohm. More distance than 4 to 5 inch will not give much more impedance.

Use not more then 1/100 wavelength distance between the feeders. E.g.:
for 10 Meters (28 MHz) the distance between the two feeders must not be
more than 10 cm (somewhat less than 4 inch). Otherwise the open
feederline will radiate which may cause LFD/TVI.

Why use coax? Just use good antennawire for your homemade open feederline.

Interesting ..... I assume this is an academic question hi hi .... I am not familiar with 8x rule in terms of useable harmonics. However, a 1 wavelength loop on 500Khz is a formidable amount of wire ... about 500' per side. Your saying such an antenna would be only marginally useful beyond 4 Mhz.

>Anybody ever discussed lowering the Q of a loop by creating a caged

I have never seen discussion on this matter. However, I have given it some thought in relation to small loops (1/10 wavelength mag loops) where high Q represents the problem of very sharp resonance. In this case I was assuming that the Q could be lowered by using copper strapping to form the loop rather than copper tubing. However, in terms of a full 1 wavelength loop it never occurred to me as it already a relatively broad resonance. Again interesting.

By near perfect loop I assume you are referring to 'near circular' ..... The area inclosed by circle vs a square (where the perimeter and circumference is the same) is increased by about 25% which for all practical terms is the 'capture' area for a loop. All the work required in your example (like building a suspension bridge) might come close to increasing the capture area by 25% .... however, I can't hazard a guess as to what it would do the radiation pattern.

>Feasable to anyone else?

The loop is a balanced antenna and in order to preserve some of its best characteristics it is best to feed it with a balanced feed line. I have more experience with vertically oriented loops and have always found the radiation pattern to be best with balanced feed line. Balanced is more important than impedance match in many cases. The arrangement you describe will come close to achieving both. However, using the twin coax route may be a bit of overkill. It will be useful in feed line runs that come next to metal objects and take bends as when you bring it into the operating position or if you have to tape the line to the metal tower. Ordinary 300 ohm twin lead or 450 ohm ladder line works vy well but you have to be more careful in how you 'dress' it. A simple tuner like a Z-match or a standard T-Match with balun will work well at the transmitter.

Hans,

If you take two pieces of equal lengths of coax, lay them side by side and solder the shields together at both ends. Then use the two center conductors as though they were twin lead or ladder line. This raises the impedance value of the line to exactly double its original value. If you use two pieces of 50 ohm coax then you have a near perfect match to a full wave loop antenna at the fundamental frequency! And, your coax is impervious to nearby metal objects such as gutters, aluminum siding etc.

You still need a tuner between your 50 Ohm transmitter and your "shielded twin lead" feed line for multi-band operation.

Great idea for passing through walls and passing nearby other objects that may react with the transmission line. The biggest detraction as far as I'm concerned is the weight. Why add all that weight to get up to your loop that may be 20 or 50-feet in the air, when you can get equally good service from much lighter balanced transmission line (homebrew, ladder line, whatever).

As I recall, as you add harmonics -as you desribe, by adding length to the loop- you do increase the number of lobes, but the lobes tend to run together. I understood this is why an 80-meter loop that is actually one wavelength on 80-meters displays greater non-covered areas than a similar 80-meter loop made with twice as much wire (twice the 80-meter wavelength in other words).

I don't have my Antenna Book at hand, but there are plenty of pictures and text covering this material.

> Anybody ever discussed lowering the Q of a loop by creating a caged

I think it would work in theory. It certainly works with other antennas. As you increase the diameter of the conductor you obtain better bandwidth, with the benefits that accompany that. This can be achieved by using a bigger diameter wire or pipe, or using a 'caged' version which simulates a larger diameter conductor.

I also think if you follow the advice of the other ham to first build this on paper, then build a scale model, and if still excited (and can afford it) building a full-scale version, you will find your answer along the way.

In other words, looks great on paper, but pales when you are standing there with your tools-in-hand trying to figure out where to plant all those masts or towers to make this happen.

This ties-in with your 'perfect circle' question too. Looks great on paper....

It should work if you have the patience for it. Buy highly resistant UV rope. You sure don't want to be re-weaving that spider web every year!

As I mentioned about your coax-made-into-balanced line... works great, but is generally reserved for problem areas due to the weight. Ladder line is a lot easier to work with than paired up 1/4-inch diameter coax, especially at 40 and 50-feet in the air!

Hi,

There is no reason you couldn't use both ! .... Low loss low weight ladder line where appropriate and the balanced coax arrangement when passing by metal objects and passing through walls etc ... no longer than necessary.

Clear Day
http://hraunfoss.fcc.gov/edocs_public/attachmatch/FCC-06-149A1.doc

The R&O released yesterday covers a plethora of stuff. On a quick read, here are my notes on things that interested me.

Novice bands eliminated. Novices/Tech+ have same CW Freqs as General on 80, 40, 15M. 80 and 40M.

Phone bands expanded, down to 3600 on 75M, down to 7125 on 40M.

Extra class phone segment on 75 expanded to 100kc (3600-3700), Advanced class similarly gets 100kc (3700-3800), General will start at 3800.

This isn't in effect yet !!! But will be soon.

1844. Fed as vertical for 160M

Yahoo group: SkyWires
Date: 2006-10-15 19:52:23 UTC
From: Tim
Topic: 1844 Message: 1844

I'm really looking for a way to get on 160M this fall-winter, so I went back and re-read the original skyloop article...where they mention shorting the feedline and using it as a top-hatted vertical.

The article mentions working the antenna against good ground. So here's my question. Has anyone gone to the trouble of putting in a ground wire system and then used their 80 meter horizontal loop in this manner? What kind of performance did you experience?

The vertical feedline to my loop is about 35-40 feet of ladder line. I feed the loop in the middle of one side (closest to my house). Because of the size of my lot, I'm reluctant to put up a different antenna for 160, such as an inverted L, because I'm afraid it might interact with the loop. There's just not enough room for two big antennas without them coming into close proximity.

I don't mind doing the work of putting in the ground system if I knew someone else had successfully used such a set up. All comments welcome.

Hi Tim,

I can tell you that this kind of arrangement works vy well. I had such a system using a 100' inverted Vee (also a balanced antenna) with the apex up on a 30' TV mast mounted on the peak of the roof of a 2 story house. The feed line was 300 ohm TV twinlead and the antenna was normally used on 80m and 20m. The shack was in the basement of the house which was hot water heated. The hot water heating pipes connecting all the radiators and furnace boiler were readily available for an RF ground. The feedline was at least 65-75 ft long from the top of the 30' mast to the shack next to the basement window.

As you said, I shorted the feed line and fed it to a tuner using the heating system as RF ground. I used the arrangement to call into a 160M net every morning all winter (all farmers) mostly in Saskatchewan and Manitoba, with the occasional Alberta rancher hi. (I was located in Winnipeg Manitoba) I used a Heathkit DX-100 AM transmitter and never missed a morning ... great signals and excellent copy.

Thanks, Jim, for the reply. I think I'm going to give it a try and go ahead with the radial installation.

I run coax from the rig through the wall to a 4:1 balun followed by the ladder line to the feedpoint. Should I make my shorting jumper for inside the shack at the tuner, or should it be done on the other side of the balun at the ladder line?

Hi,
I would do it right at the tuner in the shack unless you have a remote ATU. I am sure you can jury rig a short piece of coax to accommodate the change. Some in this group have suggested that it would be as simple as unscrewing the PL259 connector and moving the outside shield from the frame of the tuner and leaving the center pin connected .... I am sure that would work but I would go for something more substantial hi hi.

For what it's worth... I run my 40m loop on twinlead. I am able to get the loop to load on 160 through 10. To get to 160, I at first tried the shorting trick at the feedline... and the shack was filled with RF (plus it got into the telephone, the television, the baby monitor, and in my fingers.)

Then - either serendipity or stupidity (you pick), I tried loading it by driving one half of the twinlead with the random wire output on my tuner, leaving the other half of the lead disconnected. THIS puts out like gangbusters, and gets the RF out of the shack and house and phone and baby monitor. One of you guys who are good at math might be able to explain it for the rest of us... as for me, I am happiest with "cut and try" engineering, and this seems to work. My tuner is the stock AT-200(?) toroid and switch unit that part of the Kenwood TS820 transmitter setup (I also have the matching outboard VFO - never use it but it looks cool.)

ANyway - this is my $0.02 - your mileage may vary!

1849. New 80M loop Pictures

Yahoo group: SkyWires
Date: 2006-10-28 04:48:37 UTC
From: Keith Morris
Topic: 1849 Message: 1849

I've put my 80M horizontal loop skywire back up. I feed this with ladder line to a link coupled tuner.

I missed my loop. It is REALLY a nice antenna IF you can make one. (And they don't cost very much.)

You can see some pictures at: http://users.adelphia.net/~keithlm/586/

There is nothing really new here... but I do know that people like to see pictures when they're thinking about making something.

Keith,

Nice setup and I wish you lots of QSO and DX on that loop.

Mine is very similar except that its double the size but only 33ft up. I use it on all HF bands (never tried in VHF) and worked some 234 countries with it the last two odd years, including 55 on 160M.

10M was open today and I worked a number of stations in the CQWW contest, including XX9C and J3E.

I feed it directly with RG213 to a 1:1 balun but the ATU is a must (although not on 160M on its fundamental resonant frequency).

I want to try a balanced feedline sometime just to see if it makes a difference. Also considering to give it more height but as you said the height does not make much of a difference - maybe just on the lower bands.

As I have the space I'm also considering doubling the loop for that extra bit of gain and lower radiation angle on the lower bands.

I just love these loops - simple, cheap and very quiet (I have a HT power line running the length of the northern side of my plot so vertical is no use)

Hope to hear you on the bands, Keith.

Use a Discone antenna. It works great on my RDO (40-3000 mc) & AR3000. With 3 Discones & an antenna switch you can cover the whole spectrum. Cut 1 for 30-1000 mc, 2nd for 1gc-2gc & 3rd for 2-3Gc-works for me.

1861. Use 80 meter full wave loop for 160?

Yahoo group: SkyWires
Date: 2006-11-03 05:01:02 UTC
From: cewyattjr
Topic: 1861 Message: 1861

As the winter months approach I've been thinking about getting on 160. I have an 80 meter loop that worked well for DX last winter, at least getting into Europe seemed to be no problem.

I'm feeding with balanced line. Rather than make the loop bigger, would I be better off just shorting the leads together and feeding it like a big vertical with a giant capacitance hat? Or should I just bite the bullet and make it a full wave loop (as much as possible) with 500 or so feet of wire? I have the room to make it a bit bigger.

Thanks and 73,

Chuck

From my understanding (& not yet having any practical experience) the recommended minimum length is 2 wavlengths on the lowest frequency as the the take off angle is only moderately OK so for 160 work you would look at a 320mtr loop & it would need to be up high. On the flipside using your loop effectively as a 1/2 wave vertical would send the signal straight up & back again which theoretically looks worse. - Perhaps your idea of making it longer is the better of 2 evils

1863. 80m loop fed with coax

Yahoo group: SkyWires
Date: 2006-11-06 14:34:51 UTC
From: jsb@digistar.com
Topic: 1863 Message: 1863

hi,

Been reading the archives with interest but have a couple questions I can't answer...

Can I feed the loop with standard 9913 type coax without a tuner - I suppose I could but I would only be able to use it on its resonant frequency (80m in this case)?

If I run high power (1KW+) using a tuner at the rig will I destroy the coax? I don't really have a house that will accomodate ladder line because the shack is located in a room in the middle of the house - I can easily get coax out the wall of the shack through the garage and outside but everyone says ladder line won't work if it is within a foot of metal pieces. I'd have the run the ladder line near the garage door track in a few places so not sure how this would work. It would not run parallel to the track, it would cross perpendicular in a few places so not sure if that is ok.

I've got 5 dipoles hanging off of a 40 foot mast and it works ok but not as well as i'd like. I would really like to put up a 80m skywire so I can work all the bands without having a pile of antennas interfering with each other. i'd be more than happy to use ladder line if it would work, I just don't know how well it would work given that i'd have to hang it from the ceiling of my garage in the vicinity of garage door tracks. I also don't know what the preferred method is for running ladder line to the top of the mast given that the mast is metal.

Do I need to keep the ladder line 6 inches or 3 inches or a foot or more away from metal poles, and how far away for perpendicular paths?

Final question - what kind of poles are recommended for putting it up in the air? I don't trust the trees I have and I can't climb them either. I'd rather just put up 4 fiberglass poles and hang it that way. Any recommendations for where to buy good poles?

Thanks!
Jason

Jason,

With all those places to get the feedline through, over and around, I would stick to coax. Running high power on balanced line in your situation would be asking for arcing and charred wood (or worse!). Even with low power, you've got proximity problems.

One answer would be to put an automatic tuner inside where the feedline exits the building and change to balanced line at that point.
That would keep the swr on your coax low for the transmitter's sake, on all bands it would tune.

That's a discustingly neat picture of your station, by the way! :)

1865. Re: 80m loop fed with coax

Yahoo group: SkyWires
Date: 2006-11-06 16:04:09 UTC
From: Don Keith
Topic: 1863 Message: 1865

Jason, you can certainly feed your loop with coax, but if you intend to use it elsewhere besides close to its resonant frequency or harmonics, and especially if you will be running considerable power, I don't think you will be happy with it.

Open-line or window-line feed is a much better choice because there will be far less loss (expended as heat in the coax, which with high power could be enough to be damaging) and your tuner will be looking at a much easier match. By the way, a balanced tuner would be the better choice but, if sufficiently rated for the kind of power you expect to run, a tuner using a balun for balanced feedline should work okay.

I don't think crossing perpindicular to your garage door track would be much of a problem, and especially if you can keep the run a few inches away. For other metal, including adjacent to runs of coax, the rule I've always heard is keep the open line at least twice its width away and avoid long adjacent runs within a foot or so entirely if possible. I think if you standoff from your tower a foot, you'll be fine.

Some recommend using a balun outside the house to couple the higher impedance open line to a coax run into the house. Some on this reflector may have been able to do that, but I don't see how you could without compromising the broadbandedness of the loop/open line. What type balun would work? 6:1? 8:1? You may not even be able to find a commercially made one that had the right denomination, and the impedance is going to vary depending on your operating frequency. Of course, you have the same problem using a tuner with a balun, but somehow, having it closer to the tuner and not having that long run of coax facing a possible serious impedance mismatch seems to make me feel better.

Here's a compromise I used and it seems to work fine. I took two equal length pieces of coax--I used RG-8--long enough to reach from outside (or wherever you'll encounter other metal) to the tuner. Keep it as short as possible, especially if you will be running power. Tie the braids together on each end. Hook the braid on the station end to your station ground. Tie each leg of your ladder line/window line to a center conductor of the coax. Hook the other two center conductors to the balanced line terminals on your tuner. The impedance of the two pieces of coax is closer to your ladder line and should present the tuner with a better match.

Let me know how it works.

hi - lemme ask another dumb question... this is a hypothetical question only.... if I did run the ladder line so that it was perpendicular but only one inch above the track in a few places what does this do... does it set up a weird magnetic field near the track (TVI?) or does it cause the ladder line itself to couple somehow and get hot and potentially burn up on QRO transmit?

thanks,
Jason

Yes, feeding directly with coax works well on the band for which the loop was designed ... eg 1 wavelength @ 80M. You will have higher SWR on other bands.

>If I run high power (1KW+) using a tuner at the rig will I destroy the
>coax? I don't really have a house that will accomodate ladder line

>that is ok.

The main difference (not the only one) between using a coax or open wire feed line between a 80M loop used for multi band operation is that the coax arrangement will introduce greater feed line loss than the open wire line. The other difference is that the open wire line maintains loop balance and minimizes feed line radiation. Full size coax like RG8 can stand a great deal of voltage and I doubt if voltage or heat will damage the coax ... even at 1 kw. However, the problem you may find transmitting with that arrangement is that you may have to deal with excessive RF in the shack.

As far as open wire line or TV twin lead and metal objects is concerned you don't have to be too concerned. TV twin lead accessory stand-off are usually only 6" long. On a number of occasions I have run TV twin lead down metal masts using these stand-offs and have had excellent performance .... In some instances I have actually taped the twin lead to the mast and again had excellent performance. If you use higher power and 450 ohm open wire line I would of course recommend the use of stand offs of at least 6" from the mast. They shouldn't be too hard to manufacture.

Bringing the feed line through the house is a different problem ... I have used TV twin lead to great success. Some people use open wire line to the

house .... then couple the balanced line to coax (via a Balun) for the run to the operating position. Another posting suggested running a parallel pair of coax leads configured in a balanced line arrangement to the operating position.

>I've got 5 dipoles hanging off of a 40 foot mast and it works ok but not

>know what the preferred method is for running ladder line to the top of
>the mast given that the mast is metal.

Well you can experiment with multi band operation and your feed system before putting up the 4 poles and a horizontal loop. Take down your 5 dipoles and put up a single dipole (I assume you are using them in an inverted Vee configuration since you have a single 40' mast. Make the inverted vee about 100' long (50' per side) and feed it with TV twin lead for a start. A 100' inverted Vee with a 40' apex is an excellent antenna. Bring the twin lead into the shack the way you describe and connect it to your tuner via a balun. It will work like gangbusters. Once you establish the operation on the bands of your choice you can upgrade the feed system with open wire line/coax/balun etc for higher power.

You may find you don't want to make the physical and financial investment installing the 4 poles and skywire. If you do, then you will already have solved your feed system .... the needs will be almost the same whether you use the 100' inverted vee or 80M skywire.

HI Jason,

Well the way balanced line works is that the RF currents in the parallel lines generated by your transmitter (including the standing waves) are 180 degrees out of phase at any particular point along its length. This means that in a perfectly balanced antenna/feed line system there will be no radiation from the feedline as the electromagnetic fields generated in the parallel lines in close proximity to each other cancel out. The danger in running balanced feed line close to metal objects is that the balance in the parallel fields will be disturbed which will cause radiation.

The electromagnetic field around the feedline is much reduced from say a single wire (eg end fed wire antenna). The field around the balanced line is much reduced because of the balancing effect. Any effect of metal objects seem to be negligible if 1 foot away. The effect is less if the object is narrow and perpendicular rather than parallel. If you are running close to a parallel mental object it useful to put a twist in the parallel line ... eg TV twinlead or in the case of wider space open wire line .... to keep each line an equal distance from the object .... always trying to maintain balance.

In high power installations (commercial) using open wire feed systems they go to great length to make sure each of the parallel wires is affected equally by surrounding metal objects. With close spaced parallel lines like TV twin lead the effect of nearby metal objects is much less critical

than 450 ohm line and much much less than home made wide spaced line that has 4" or more separation.

When dressing open wire parallel feed line the objective is to minimize the disturbance to the balance of the electromagnetic fields and thus radiation from the feedline.

From: erik@n0ew.org
Topic: 1863 Message: 1871

The original poster had a 40-foot tower, which already supported
several dipoles.

So I took this to mean using the tower as the tallest point of the
inverted vee antenna, and the feed point for the antenna, and each leg
of the antenna to be 50-ft. in length.

Rules of thumb would say to aim for at least a 120-degree angle
between those legs. Practical rules will first ask where the support
points are located on the property and then get as close to horizontal
as possible, and leave it at that, be it, 90-degrees, 150-degrees, or
x-degrees.

We might add that keeping the end-most tips of those legs above the
earth to be a good idea. Rule of thumb says 10-ft. is good. I'm not
personally certain wether that is so much due to earth effects upon
the antenna, or being pretty certain no neighborhood kids are playing
with your antenna when you transmit.

Good rule of thumb in either event.

I was referring to the fact Jason mentioned that he was using a 40 ft metal mast. I was saying that a 100 ft inverted vee antenna fed with TV twin lead with the apex at the top of the 40 ft mast makes an excellent all band antenna.

I've got a 160m dipole that I may retrofit with ladder line once I find a tuner. it's currently fed with RG8X but I feel empowered to get 86' of ladder line and a tuner to try it out. i've got the room to put up a 160m loop also, so now it's Tuner hunting time for me.

Thanks!

1874. reuse old copper?

Yahoo group: SkyWires
Date: 2006-11-06 21:17:46 UTC
From: jsb@digistar.com
Topic: 1874 Message: 1874

I've got the remains of several dipoles that I took down a few years ago. When I took them down the wire had tarnished a bit and I couldn't ever get solder to take to it to use on other antennas, even with some flux. I used radio shack paste flux so perhaps it wasn't up to the job. But I was wondering if I could clean that up some other way and use that wire instead of buying a spool of new wire. I read here and there where you can remove the tarnish from copper for antiques restoration but I also read that some of those anti-tarnish ideas can screw up the conductivity of the copper.

Anyone got any good ideas how to remove the tarnish off the last inch of each piece so I can solder it together into one long piece of wire?

thanks

OK,
Well I use 125 to 145* apex angle
As far as the end of the wire goes if you have good ground conductivity you should try to keep the ends a 1/4 up from the ground.
Difficult for most hams who have an 80 meter dipole.
Thats why I use an end fed for 80 because I just use a tiny home brew tuner and I put the wire right to the center conductor on the back of the rig.
I built up several loops but never got into the larger ones.
I sort of stick the 3-4 foot diameter MAG loops.
They seem to do good for what they are
It;s got more hams like me back on the air because were not allowed any wires.
They actually hunt down 32 GA magnet wire.

Jim, VE3CI, says much of what I did only much better! And his suggestion on another post about twisting the balanced feedline is another trick I've learned. It not only helps to keep it from coupling with metal objects it may pass but it also keeps wind resistance down.

I use 450-ohm "window" line, primarily because it is easy to handle and relatively cheap (or as cheap as anything with copper in it these days). I buy mine from The Wireman but there are several suppliers. If you buy the line with stranded conductor (best choice) Be sure to tin the wire with solder after removing the insulation or you'll have a mess trying to solder it to anything.

And Jim is also absolutely correct about trying a balanced-feedline dipole at 40 feet. I'd make mine longer...maybe 135 feet total for

80/75 or 270 feet for 160. It should then be a fine antenna for all ham bands, maybe even including six meters if you have a matchbox that can handle it. My 450-foot loop is working well but I'm itching to try the longwire, too. Literally itching! I got into a mess of poison oak when I was putting up the skywire!

Good luck!

I can't think of a good reason why you shouldn't re-use the wire. As for cleaning the tarnish off the wire so you can solder it, I'd guess there is some kind of copper cleaner at a hardware store. I believe I've taken sandpaper to copper wire, too.

1879. 160 or 80

Yahoo group: SkyWires
Date: 2006-11-07 01:02:13 UTC
From: Jason Buchanan
Topic: 1879 Message: 1879

hi,

I took a walk around the house earlier to get a rough idea where I can put up different loops. I can put up an 80m full-wave skywire loop that is clear of trees, etc. in open field OR I can put up a 160m full-wave loop that will partially have to be "threaded" through the trees. I?m not sure if this is a good or bad idea. I?d sure like to be on 160m but if it?s not possible then I?ll go the 80m route.

The shape of the 80m loop is not perfectly square though. From the feedpoint (corner) I have 68 feet to a good tree on the left and right side of the loop but the distance from the feedpoint to the 2nd pole is probably about 50 feet. It was dark by the time I finished measuring out the sides. So I guess it would look more like a rhombic with the feedpoint on the obtuse "wide" side of the angle rather than the acute "narrow" side.

The shape of the 160m loop would be more rectangular and be 20 feet at most above ground. I would have to run the wire through the trees here and there along the property line. The northwest corner of the loop would be 10 feet lower than the other corners because that part of the yard slopes down about 10 feet at the far corner. Eventually I could get a fiberglass pole or something to support it higher but initially I would secure it to a tree about 10 feet off the ground.

So..... just curious what everyone's opinion might be about what the pros and cons would be for either antenna. A squished 80m loop (very broad to east/west) or a more rectangular 160m loop about 20 feet off the ground with the NW corner about 10 feet down.

Thanks!!
Jason N1SU

I looked but I missed the post or there was no mention of the wire being solid or strand.
Anyway I cleaned the ends of stranded wire by fanning out the strands then scraping the fine wires with the edge of a knife.
I twisted both ends together and used a 150 watt iron and the hot solder just works itself into the twisted joint.
You shouldn't need any flux and come to think of it I can't ever recall using any type of flux on wires or on PC boards
When you twist the ends together hold the iron under the joint and keep heating it until solder will flow from the top, through the twisted joint down to the iron

Try dipping the ends of the wire in some muriatic acid, rinse them with water, twist them together and solder.

Try dipping the ends of the wire in some muriatic acid, rinse them with water, twist them together and solder.

Regards,

Dennis

My favorite trick (which works on copper-bottom pots as well) is to mix up some vinegar and salt (lots of salt) and then dip the ends in, twist them between your fingers to get the strands all covered, then rinse well... I've also used baking soda after the rinse to neutralize the vinegar... then rinse again.

Works like a charm... and the ingredients are in your kitchen cupboard, not the garage ;-)

What about Tarn-X? It's the stuff that in the advertisement has an old, corroded, tarnished penny half in and half out of the liquid. The half that's in looks brand new. My wife, my mother, and even my grandmother use it. Without any scrubbing, I have seen it make copper look brand new before.

Has anyone tried Tarn-X for this application?

1886. Re: 80m loop fed with coax

Yahoo group: SkyWires
Date: 2006-11-07 15:17:46 UTC
From: Jim Coe
Topic: 1863 Message: 1886

Jason,

I second what was put forth by Don (N4KC) with some slight differences:
>Here's a compromise I used and it seems to work fine. I took two
>equal length pieces of coax--I used RG-8--long enough to reach from
>outside (or wherever you'll encounter other metal) to the tuner.
>Keep it as short as possible, especially if you will be running
>power. Tie the braids together on each end. Hook the braid on the
>station end to your station ground. Tie each leg of your ladder
>line/window line to a center conductor of the coax. Hook the other
>two center conductors to the balanced line terminals on your tuner.
>The impedance of the two pieces of coax is closer to your ladder line
>and should present the tuner with a better match.
>Don N4KC
I regularly use two lengths of RG-8 or RG-213 (up to about 15-feet,
shorter is better)
to route RF from my indoor tuner to my outdoor loops fed with open
wire line. I connect
the braids together only at the shack end and tie them to my tuner or shack
ground. I leave the other end of the braids open and just seal the
ends with coax
seal. I do it this way as I have seen some impedance bumps on the upper bands
(17m and 10m) when the shields were connected at both ends. I do not use
RG-58 or RG-8X simply because of the lower breakdown voltage ratings as I
often run legal limit SSB and AM. The paralleled coax will result in
approx a 100-ohm
line, but the mismatch to the 450-ohm or 600-ohm open wire line will not be a
problem. Tape the two pieces of coax together every 6-inches or so to keep
the balance under control.

I do not recommend the use of a balun at the end of a single coax run from the
shack to convert to open wire line because the high impedances and high RF
voltages involved. Also, the impedances you will see at the junction
of the coax
and open wire line will vary all over the place and a 4:1 balun will seldom see
a 4:1 matched condition.

As for the open wire line itself, I use only the W7FG open wire line.
It is nominally
600-ohms, is very sturdy and I have experienced no failure of any
kind with it in
the five years I've used it. Even the best windowed 450-ohm line I've used has
experienced breakage due to wind and ice during the same time period.

As for a tuner to use, do not try to use a tuner which has a balun at
the output to

match open wire line. The balun will seldom see it's design values of
impedance,
will saturate easily and may even experience voltage breakdown. Either move the
existing balun to the input of the tuner or better yet, buy or build
a true balanced
tuner such as the one described by Rich Measures, and others, in the
ham magazines.
I use a balanced PalStar and a homebrew balanced tuner.

Another problem a lot of hams have with loops and dipoles fed with
coax or open wire
lines is that certain feed line lengths will result in extremely high
(or low) impedances
or high RF voltages at the tuner end of the line on specific bands.
Often, this will either
cause RF in the shack or will be such that the tuner cannot match the
line. One solution
is to be able to insert (or remove) a section of line to avoid the
problem on that band.
A second solution is to install the line using a non-resonant length
to begin with. The
ARRL and other handbooks list lengths to avoid in the sections
related to conductive
guy wires for towers.

I'll give that a try. I've got a pile of RG8 that i'm not using which
would make a good test run.

I bought one of those ladder lock gizmos to take the ladder line and
connect it to the loop.

> As for the open wire line itself, I use only the W7FG open wire line.

I will look for that. A local ham gave me a 100' piece of 450ohm #16AWG
ladder line to try - will see how that goes and will look for the line
you're talking about.

> As for a tuner to use, do not try to use a tuner which has a balun at

I picked up a Dentron "Super Super Tuner" (the big 3KW PEP model) -
wondering if that would be ok?

> Another problem a lot of hams have with loops and dipoles fed with coax

I have a run about 60 feet maximum from the shack to the antenna mast. I am going to cut it away from a multiple length of the bands. I found a neat page by KV5R http://www.athensarc.org/ladder.htm about non-resonant lengths of 43 and 86 feet. I don't think i'll need 86 feet to get to the antenna but I can put some of the excess outside along the foundation of the house.

thanks!
Jason

HI,

Use some steel wool .... or better yet get a sheet of emery paper .... you
will see clean bare copper in no time flat.

"Try dipping the ends of the wire in some muriatic acid, rinse them
with water, twist them together and solder."

Remember that inhaling the fumes from heated MURIATIC ACID is very
toxic and should be attempted only in a well ventilated area. i.e.
The use of fans are recomended.

When you mentioned MURIATIC ACID a light bulb when off in my memory bank..
I seem to recall a teacher telling us to be ultra carefully with that
stuff....
Personally, I would stay away from muriatic acid....
If I have wire that was oxided.. I would try scraping it with a knife
first....

1891. Naive question...

Yahoo group: SkyWires
Date: 2006-11-07 22:08:45 UTC
From: renopithicus
Topic: 1891 Message: 1891

I don't have the real estate to build a horizontal loop that's cut specifically for the frequencies I normally listen on. Now, I know that when someone wants to use a relatively short wire they can attach it to a matching transformer and it will have a more even frequency response as you move from one end of the HF spectrum to the other. This makes it more useful as a SWL antenna. I wonder whether this is true of loops as well? If I made a relatively small loop (say 80 ft total length) but fed it with coax and a matching transformer, would it be effective on HF? And would it have any of the characteristic strengths of horizontal loops (low noise, e.g.) or would it be functionally equivalent to a random wire?

Thanks in advance.

1892. Homebrew 2/440 mobile help needed

Yahoo group: SkyWires
Date: 2006-11-07 22:37:11 UTC
From: icra@galaxynet.com
Topic: 1879 Message: 1892

My VHF antenna reference books are in storage and cut off by standing water......

Currently have a Hustler 5/8 2mtr mag mount....works great for 2mtrs but not at all for 440...

Looking to either home-brew a 2/440 mobile antenna with gain (not just a 1/4 wave 2mtr antenna) or add to the Hustler to get 440 on it also....

My thoughts were to use some of the fiberglass rod for electric fences and put a 5/8 wave 2 mtr antenna on it and a 440 1/2 over 1/2 wave 440 collinear and heatshrink over the whole thing. Is this do able? Any advise on how to do it?

My other idea (should be easier and faster to do) is to add a strip or steel to the bottom of the Hustler and put the 440 antenna up from it. Advise on how to do this?

Mel and the Group,

I was getting ready to post something very similar to yours. I have a the same problem and I have been looking for a solution but I have not found one as of yet. I took a wilson little will antenna and took out the coil and hooked the center conductor from my coax to it and put in a piece of fencewire about 19inches long. The thing works good for vhf but I have no idea how to add uhf to it. Im like you Mel, if you find something let me know.

Thanks,
Joey

>Thanks in advance.

You don't mention the frequencies you normally listen on. You mention SWL ... so I assume you are talking about receiving antenna only. An 80' loop is not really a small antenna hi hi as it is a full wavelength loop at a frequency just about in the middle of the HF spectrum .... eg around 12mhz. I am sure you could couple to it with an RF transformer wound on a ferrite core and it would make an excellent receiving antenna for SW.

The transformer would not provide uniform matching across the spectrum as such a loop would represent quite a range of impedances ..... however for receiving that should not be a problem as modern receivers have plenty of gain and close matching is not necessary. It is more important to locate the antenna as far from local noise generating devices as possible. However, if you want to use an 80 ft loop to transmit on the amateur bands from 160m to 10m that is a different story. You will not get effective power coupling coax to loop using a simple RF transformer for the reasons already mentioned. That doesn't mean that an 80' loop isn't an effective transmitting antenna right across the spectrum .... but it is only naturally resonant at 12 mhz .... at other frequencies you will have to tune and match the loop to the coax. or use a balanced feed line.

In fact SGC advertises an identical 80 ft loop as an all band antenna when tuned (at the feed point) with their remote automatic antenna tuners (they call them antenna couplers). I have used this kind of antenna using the SGC technique with a remote antenna coupler as well as the more economical method of feeding it with an open wire feed line (TV twinlead). The antenna would be a square 20' to a side. It is possible to arrange the 80' into a 2, 3 or 4 turn loop and resonant it across the hf spectrum .... but then it wouldn't be what you would call a 'skywire' hi hi. It is an effective antenna .... but as with most antennas, the higher you mount it the better it works. PS

If you can get it high enough I can assure you that you will work the world on 40-15 mtrs.

1895. loop tilt

Yahoo group: SkyWires
Date: 2006-11-08 02:45:42 UTC
From: Jason Buchanan
Topic: 1895 Message: 1895

hi,

I'm curious how the tilt of the skywire affects its radiation pattern
and possibly the take-off angle. If a corner-fed skywire is fed higher
than the other corners does the antenna push the signal into the
ground... or does a tilt counteract a high take-off angle...

Thanks

OK, so that's new to me, I hadn't heard that the minimum length for a skyloop is 2 wavelengths -- I've also heard that what is recommended is using the loop most effectively is odd multiples of the fundamental wavelength.

Just curious of others have the same/differing thoughts?

1897. Re: [SkyWires] Use 80 meter full wave loop for 160?

Yahoo group: SkyWires
Date: 2006-11-07 14:35:56 UTC
From: charles Allison
Topic: 1861 Message: 1897

Chuck,

Reccommended loop height tends to be 20-40 ft. But this seems to be for using a 40 or 80m loop on 20-10m for great dx. Most people don't tend to use a loop for dx on 80m, more likely, they use it for regional - state wide communications.

What is happening with the loop at its fundamental frequency very much depends upon height over ground. When the height is only 20 ft above ground with an 80m loop on 80m, the major radiation of the loop is almost straight up. This creates an NVIS style antenna which virtually blankets the state of TX with a good signal - far better than my 80m vertical which has a much lower angle of radiation.

As you go up in frequency to higher multiples of the fundamental loop frequency, the angle of major radiation is reduced - making it more suitable for DX and less useful for NVIS (which is pretty much good only on 80 and 40). Also, when you go to 2x the fundamental loop, the results are not real good. See the Super-loop write up for a clever way to automatically turn an 80m loop into a pair of 40m loops.

What happens if you do a 2 wavelength loop is that your major radiation angle drops from almost straight up to closer to 45 degrees. However, the loop isn't going to want to work as well at 2 wavelengths. It should be perfectly happy at 3 wavelengths and the angle will be even lower.

Again, this is primarily a problem with lower frequencies and of not being able to get the loop up to a substantial fraction of a wavelength. However, we have our 80m loop at 12-15 ft precisely in order to take advantage of the NVIS mode and the improvement over my vertical for most of the state of TX is in excess of the equivalent of going from our normal 100 Watts up to 1000 Watts were I to use the vertical - and the effect is on both transmit and on receive - and the loop provides us with a lower noise rx antenna than the vertical or our g5rv inverted vee. However, 80m DX is not in the arena of our interests except the occaisional contest.

We had been planning a 1 wavelength 160 loop and had acquired the wire and the 36ft pushup poles 2 years ago. So far, we have not tried to put it up and I'm not sure we will. I think we will do something else - to be determined.

Going to 3 wavelengths on the 160 is quite a chunk of real estate and wire. The practical problems of such an antenna might be more than its worth. It's also questionable just how much improvement you'll get over lesser loops but at least on paper it says it's better.

best regards,

Charles

Topic: 1863 Message: 1898

Jason,

You can find the W7FG open wire line by doing a Google search. They primarily sell manual copies for radio gear, but also sell open wire fed dipoles and open wire line. www.w7fg.com

The Dentron is one of the better tuners available, but it has the balun at the output. That puts the balun at the point where it will experience wide swings of impedance and RF voltages and that is tough on baluns. Take a look at Rich Measures site for info on balanced tuners. www.somis.org

From: Jim Coe
Topic: 1861 Message: 1899

Chuck,

My experience is if the loop is a full wavelength on 160m, then it will be hard to match on 80m. If it is a full wavelength on 80m, then it will be hard to match on 40m, etc.

I don't tend to use my loops on 30m to 10m, so I don't have a lot of data to share. My experience does seem to support the odd wavelength issue you referenced.

I use open wire line to feed my loops and use a balanced tuner, not an unbalanced tuner with an output balun. If you feed the loop with coax, I would guess the problem might be worse.

From my first paragraph above, it would seem that using 3 wavelengths or 5 wavelengths would minimize the "next band" problem I have seen on the 160m, 80m and 40m bands.

Chuck:

I like WB5IZD's answers to your questions. Truth is, most of us can't put up a quarter mile of copper wire, and we certainly can't hang it 200 feet in the air at all points. I'd put up all I could, not worry about how long it was (so long as you get at least a wavelength on 160, though shorter will certainly work), and hang it as high as you can. If it ends up 20 feet off the ground, you will have a very effective 300-to-500-mile 160-meter antenna.

My own loop is 470 feet long and varies in height from 35 feet to 15 feet. That's where the tree limbs were! And I consistently work (with good signal reports) into East Texas, Kentucky, South Carolina and Florida from Central Alabama with 100 watts on 160 meters...when the QRN is not too daunting. I don't expect DX on 160 with this antenna, but I did get into South America on 75 several times in the past month. Still, it will not be a stellar DX antenna on those bands.

On higher bands, you do achieve gain over a dipole, but you also get multiple lobes with sharp nulls...the higher the frequency, the more lobes and nulls. You're stronger than dragon's breath to one station but another a few hundred miles away from the other has trouble hearing you.

And one of the advantages of a loop is you don't have to worry about even and odd multiple wavelengths. It should work equally well on all of them if you are feeding with balanced line and tuner.

Try it!

Well, Rule #1: If you make contacts that you are interested in making, the antenna works just fine for you.

I have heard that rule of thumb about the loop antenna being twice the lowest band you plan to operate upon. But a friend and I have used a square footprint 80-meter loop (about 30-ft tall) a couple times at field day. Works great. Including 80-meters, although that band was normally only used in the darkness hours, so it didn't account for the majority of contacts (I'm just guessing really - going by memory of the events, not comparing logs of any kind).

I may be wrong, but I seem to recall the x2 lowest band suggestion is mainly to get the area of coverage to be closer to a circle, as opposed to a four-lobe pattern. (The ARRL Antenna Book has a section that shows these patterns pretty well. I may not be remembering this correctly, so double check me on that.)

Height is a major factor in take off angle. One big exception is vertical antennas, which is why many DXers like them.

My loop is very bent and twisted. It certainly isn't that neat appearing square skyloop you see on covers of books!

For starters it is 3-sided with a small vertical portion.

Exit the shack window at the corner of the house (one story). Likely become unbalanced at this point. Then go up and slowly outwards to about 12-to-15-feet height. From here (the lowest point) each wire shoots off in a difference directions, both to trees. One at about 40-45-feet height, and one about 50-60-ft-ht. Then they connect to one another.

Why?

That is what fit my land and tree layout the best.

So study as much as possible, get an many opinions as possible (remembering some of them will be wrong because (1) they aren't looking at your setup or (2) some people just don't understand where their knowledge stops), and then look at your situation.

Whatever antenna(s) you put up, they must always fit the property in which they'll reside. Apartment dwellers have different major concerns than poertable operators, who are challenged differently than mobile operators or home owners.

So good luck, and take time out to build some experimental antennas. They can be cheap and a lot of fun to play with!

Keep reading, and keep asking questions! Hams are seldom out of opinoins! Hehehe....

1902. Feeline length for loop used as multiband antenna...

Yahoo group: SkyWires
Date: 2006-11-08 22:09:42 UTC
From: zendoc62
Topic: 1902 Message: 1902

Hello Group,

I'm new to your group and have recently put up an 80m full-wave loop which I'm feeding with 300 ohm ladder line. I use the loop as a multi-band antenna from 80 through 15 m. I use an MFJ 993b to match the system.

Can anyone tell me if there is an optimal length of ladder line to feed this antenna for multi-band use? I'm sure the question has been asked many times before but I couldn't find a direct answer in the archives.

Many thanks and 73 from down under,

John

From: Paul MW0CDO
Topic: 1861 Message: 1903

Hi Chuck,

I have a 60m tilted loop up presently, and have had 50 and 40m versions previously.

The current 60m of wire is in a rectangular shape and is supported at the perimeter of my 60ft X 30ft back yard.
My 2 storey house is at one end of the back yard and the shack is on the top floor in a spare room overlooking the yard.
At the house end of the yard I have 2 6m (20ft) fibreglass fishing rods supporting the loop, and at the far end of the yard I have 2 30ft aluminium masts with 20ft fishing poles attached to the top sections.
So the loop slopes from around 50ft AGL down to 20ft AGL over what is normally good wet ground about 1/2 mile inland from salt water.
The feed point is in the centre of the house end 30ft wire and in fact is simply an extension of the rest of the loop coming in through the window (I used thin wire about 1mm diameter) and into an SGC-239 auto tuner.
The "feed line" could be thought of as parallel lines about 2 inches apart.
The SGC seems perfectly happy with the loop and will tune it on all bands 160 - 10m.
The loop is quite reactive on 80m, the SGC gets warm with 100w RF. All other bands are fine.
I can work EU, UK and eastern NA on 160m phone with 100w. NA reports range from 56 - 59+, propagation / QRN allowing.
UK and EU reports vary as well, but most contacts seem to think the loop is doing a good job bearing in mind my restricted real estate.
There's just no way I could have a 132ft inverted L or end fed or inverted V etc.

As a bonus it really holds it's own on 40 & 20m as well, excellent reports from EU on both bands.
I haven't really tried it much on 17, 15, 12 or 10m as propagation hasn't been good when I have the time.
I've worked NA on 80m with similar loops as well, reports are on average 2 - 3 S points better than my ground mounted Butternut HF6v, but the vertical doesn't have much of a radial system.. 4 X 40ft buried wires.
I have also used a manual tuner with the 40 and 50m loops, and could match them both on all bands but 80m has always been a problem.
I melted the inductor supports in a MFJ-949e tuner while running 100w on 80m, no problems at all on 160 though.

I say just put however much wire you can get up as high as possible and try it.

You can see some pictures of my current loop at < HYPERLINK "http://homepage.ntlworld.com/paultom/"http://homepage.ntlworld.com/paultom/

>

Of course your particular mileage may vary!

73..

Two off-hand answers come to mind.

1. The ARRL Antenna Book has a table with lengths of guy wires to
avoid. You could use one of these lengths.

2. (What I'd do) Run whatever length fits. If you find a trouble spot,
make a method for adding a length of additional transmission line.
This will alter the impedance.

What size vehicle?

1/4-wavelength on CB is around 8.5 to 9-feet. Obviously you won't get a full wave square loop. Too wide. So if you do this it'll be a rectangle, or smaller than one wavelength.

I am not certain this is a good plan due to the frequency. CB is too high to allow NVIS (Near Vertical Incident Skywave). That is where the RF goes pretty close to straight up, bounces off the atmosphere, and back down. This allows good coverage of large regions.

But CB is too high frequency. It'll just cut through the atmosphere. 40-meters is about the highest frequency you can use and have reliable NVIS effects (7 MHz).

This is the main reason I don't think this is a good plan.

Going with the traditional vertical antenna (of whatever flavour) will propagate more outwards, providing good coverage for mobile cb.

That's my 2-cents!

Hi Jim (and everybody else)!

Thanks so much for your thoughts on this. I'm not so much interested in NVIS as DX, and be as it may, I've had pretty good experience last winter working into Europe from here in New England around 3800 kc on 75 meters. Granted some were super stations with vertical arrays!

Probably the same thing couldn't be replicated on 160, tho'. Dang verticals are so noisy though.

I can say that my 80 meter loop has done very well on 20 meters, and with a modest amp, I felt that I could actually compete in some of those awful pileups. More recently I've enjoyed PSK31, a low power mode, and it works great for that on 20 meters as well using 15-20 watts. I suppose like others on the thead have mentioned, there would be awful nulls and fabulous lobes.

Fun stuff...

-Chuck

Chuck,

Reccommended loop height tends to be 20-40 ft. But this seems to be for using a 40 or 80m loop on 20-10m for great dx. Most people don't tend to use a loop for dx on 80m, more likely, they use it for regional - state wide communications.

What is happening with the loop at its fundamental frequency very much depends upon height over ground. When the height is only 20 ft above ground with an 80m loop on 80m, the major radiation of the loop is almost straight up. This creates an NVIS style antenna which virtually blankets the state of TX with a good signal - far better than my 80m vertical which has a much lower angle of radiation.

As you go up in frequency to higher multiples of the fundamental loop frequency, the angle of major radiation is reduced - making it more suitable for DX and less useful for NVIS (which is pretty much good only on 80 and 40). Also, when you go to 2x the fundamental loop, the results are not real good. See the Super-loop write up for a clever way to automatically turn an 80m loop into a pair of 40m loops.

What happens if you do a 2 wavelength loop is that your major radiation angle drops from almost straight up to closer to 45 degrees. However, the loop isn't going to want to work as well at 2 wavelengths. It should be perfectly happy at 3 wavelengths and the angle will be even lower.

Again, this is primarily a problem with lower frequencies and of not being able to get the loop up to a substantial fraction of a wavelength. However, we have our 80m loop at 12-15 ft precisely in order to take advantage of the NVIS mode and the improvement over my vertical for most of the state of TX is in excess of the equivalent of going from our normal 100 Watts up to 1000 Watts were I to use the vertical - and the effect is on both transmit and on receive - and the loop provides us with a lower noise rx antenna than the vertical or our g5rv inverted vee. However, 80m DX is not in the arena of our interests except the occaisional contest.

We had been planning a 1 wavelength 160 loop and had acquired the wire and the 36ft pushup poles 2 years ago. So far, we have not tried to put it up and I'm not sure we will. I think we will do something else - to be

determined.

Going to 3 wavelengths on the 160 is quite a chunk of real estate and wire.
The practical problems of such an antenna might be more than its worth.
It's also questionable just how much improvement you'll get over lesser
loops but at least on paper it says it's better.

best regards,

Charles

Hi Jason,

Pulleys work great .... and rope last almost forever. However, A trick I have used with rope over tree branches is to make the rope double where it fits over the branch ... with one rope tight and the other loose. If a rope brakes the other one keeps it up. I just lower the rope and replace the double (over the tree) section hi hi ... After all, unless you climb the tree and tie the halyard to the branch there will always be some wear at the point the rope crosses the branch. I never climb the tree .... I use my slingshot and fishing pole .... and it is pain if the rope parts and comes to the ground hi hi. And be sure, the rope always breaks sooner or later.

Jim

If you are mainly interested in getting one station , you should try a rhombic antenna .

The rhombic antenna is WIDELY used for long-distance, high-frequency transmission and reception. It is one of the most popular fixed-station antennas because it is very useful in point-to-point communications.

Advantages

The rhombic antenna is useful over a wide frequency range. Although some changes in gain, directivity, and characteristic impedance do occur with a change in operating frequency, these changes are small enough to be neglected.

The rhombic antenna is much easier to construct and maintain than other antennas of comparable gain and directivity. Only four supporting poles of common heights from 15 to 20 meters are needed for the antenna.

The rhombic antenna also has the advantage of being noncritical as far as operation and adjustment are concerned. This is because of the broad frequency characteristics of the antenna.

FB on rope trick. I will do that - anything to save hassle later. This
kind of work is done fairly easily in the late fall or winter but by
summer time the poison ivy makes it impossible to get through the woods.

I picked up some cheapie pulleys at Ace Hardware for the middle sections
of the loop and for the corners I got some nice marine grade Harken #224
microblock free running blocks (see
http://www.westmarine.com/webapp/wcs/stores/servlet/producte/10001/-1/10001/245853/0/0/harken%20block/All_2/mode%20matchallpartial/30/0
for details). The #224 block is good for 200lbs and the sheave is delrin
so conductivity should not be an issue even if the insulation wears
through. The Harken blocks are on sale ($7 bucks ea.) - thankfully it was
a quick 10 minute drive to Woburn during lunch.

Greetings...
Unless I missed something, may I make a suggestion....
Connect your antenna, via an egg insulator, to the rope.... Run the rope through the metal pulleys.. Don't run the antenna wire through the pulleys....
As the wire is pulled through the pulley, the charactoristics of the antenna will change...

From: Dave Marling
Topic: 1911 Message: 1918

I picked up some small nylon pulleys a few years ago at a Lowes or Home Depot while in the USA. They are about 2 5/8" in diameter. I use a rope over the tree top to a bungee cord with hooks on each end. The rope fastens to one hook and the pulley to the other. I also have a safety line of heavy twine double the length of the bungee in case the latter breaks.

I usually have to replace the bungee every two years while the rope (3/8" polyprop) has lasted for over five years.

HI All,

I use metal pulleys on the Loop itself and then on the ropes I also use metal pulleys. That way it do not worry about the pulleys de-tuning the antenna. The Loop will float in the four pulleys that suspend the Loop. It makes it handy to be able to raise and lower the Loop for maintenance and tuning. I am using a 160 meter full wave Loop and am just now getting it in the air. I have used this configuration before with good results. Using 450 ohm ladder line for feeding the Loop it loads on all bands using an old Heathkit SA-2060 tuner.

I've have read from the Cebik articles that a min of 2 wavlentghs at a good hieght above ground will radiate its main lobe at around 53% off the wires angle. Having a 1 wavelength loop It seems logical to me its just like a 1 wave vertical loop whereas the main lobe it is 90% off the wire. Place the same vertical loop horizontal & your signal goes straight up again at 90% & its mirror 90% towards the ground that would distort the pattern asit shot back up in the air (perhaps at a slightly better angle than 90%. I must admit I've read Cebik's article at least 20 times & what I've quoted is from memory.

In the ideal horizontal loop world that we sometimes dream about a good loop at say 160mtr band would be 4 x 160m = 640mtrs in length & near perfectly circular fed with 200 (or perhaps 300ohm twinlead) & at least 80mtrs off the ground (but preferbly much higher. That way you get 8 main lobes in all directions with a takeoff angle of 14deg or less (as the higher you raise the loop.

Pls tell me if you think Im wrong because I would appreciate any other thoughts to help me grasp this concept even more.

Thanks

That explanation certainly makes sense to me. So, what it tells me is that I might do better to get something like a Carolina Windom, in terms of angle of radiation on 160. Not sure how it would compete with a loop on other bands.

On the other hand there are always the practical experiences: For examplle, 75/80 meters was hopping last night, and I did hear folks running full wave 80 mtr loops doing quite well with European DX. Granted these were east coast stations, but seems like they most be getting some low-angle radiation to get across the pond and compete in the pileups?

Cesar, in general, full wave delta loops have an impedance close to 100/120 ohms. So, the 2:1 balun is recomended. Notice you could substitute the balun for a quarter wave (electric) lenght of 75 ohms coax, then add 50 ohms coax to the rig. Remember to apply the velocity factor when calculating the 1/4 WL. Of course the impedance seen by the rig will be OK only for the 40m band, in this case.

Cheers!

hi,

Got the tuner hooked up a couple hours ago and have made lots of good contacts on the loop. Great reports by all stations. I was pretty sure it would work but I didn't know it would work this well! Signals buried in noise are easier to copy than with my existing dipoles (I left them up for comparison and they are 40+ feet away).

I guess the main thing that strikes me is it is quieter and signals received are stronger.

Many thanks to all for help and recommendations!

Hi Jason,
I remember the first time I put up a loop . It was so much quieter, I thought it didn't work, until I tuned across a signal .

Will do for sure - I was up until after midnight last night enjoying its huge ears on 80 meters! I really have to crank the RF gain back now as there's so much signal coming in.

thanks,
jason

Subject: Re: [SkyWires] which balun?

Cesar, in general, full wave delta loops have an impedance close to
100/120 ohms. So, the 2:1 balun is recomended. Notice you could
substitute the balun for a quarter wave (electric) lenght of 75 ohms
coax, then add 50 ohms coax to the rig. Remember to apply the velocity
factor when calculating the 1/4 WL. Of course the impedance seen by the
rig will be OK only for the 40m band, in this case.

Cheers!

hi ace,

my nickname is kc. its apex is tied with a pulley on an old coconut treeand the two corners are tied also to a tree. The angle from the coconut tree to the other two corners is about 45 degrees and the orientation of the side near my shack is east-west. I made them equilateral, the feedline is connected to a 1:1 balun right now - for the simple reason that i have not made a simple connector to the feedline. I still have to cut about 2.4 meters to become resonant at 7.05mhz - which is the midpoint in our 40m allocation here in the Philippine Islands. right now I'm using a manual tuner to lower the swr to 1.1 from 2.5. From the balun I have a tranformer rg59 cut to about 21 ft. then the 50 ohm coax.

Jason:

I'll add my congrats on the antenna (and my envy for your ownership of that beautiful Drake gear!). I know you have learned a lot with this project. I know I did as I researched, built, tested and continue to tweak mine. The nature of our hobby is that there are fewer areas in which we can experiment, and one of the best is with antennas. I've had my own loop up about six weeks and I'm having a blast with it. Hard to tell at this point but I believe it is the best antenna I've ever had. On some bands and under certain conditions, the G5RV or my vertical do slightly better, but the skywire consistently wins in most cases...and it lets me work efficiently from 160 through 10 meters.

It's 60 feet short of a full wavelength long for 160 and it's only anywhere from 15 feet to 40 feet above ground. It runs through tree branches all around its perimeter. I'm using the dual-coax method of getting from the twin lead outside into the tuner in the shack, and I'm not using a balanced tuner (it's an MFJ-993B

Intellituner's "balanced" input).

But the bad boy works beautifully! I'll look for you on the air.
Please do the same.

Hi KC ,
I am using a 272' horizontal loop , it's SWR is flat at 3875 khz without any tuner. No balun here just a RG11 transformer down to the RG 8 that runs to the rig. My rig has a built in auto tuner that I sometimes use . When I run one of my amps I use a manual tuner .

I will take photos this saturday, for now the details:

I took my 160, 15 and 17 meter dipoles down so I don't have them for A/B comparisons but the 20 and 40 are still up. In my tests the receive performance of the loop has met or exceeded my inverted vees on the CW portion of the band where they are cut. The dipoles are definitely noisier and by using some tricks with MixW I do not see that the noisier dipoles have any stronger signal reception - the dipoles are down slightly with more noise where the loop has less noise and more signal. PSK and other digital modes show an improved SNR over the dipoles regardless of the distant station's location around the globe. The VK9CCG DX this morning was easier to copy with the loop.

Even if the loop had equivalent receive performance to my dipoles the loop to me is clearly the winner as I can use every HF band, top to bottom, QRO and with more signal to the radio. If I had only enough space for a 20 meter loop I would put that up. Dipoles are a real bore after having been spoiled by the loop.

I like the ability to run CW near the bottom of 160m and then go to the top and work AM with only a minor touch-up on the tuner. 80 meters works wonderfully, same for 40 and 20. I haven't been home during the daytime to put 20 meters through its paces but I will this weekend.

I use VE3SUN's DX Monitor for spots - it's a thrill to have every HF band displayed and know that I can use each one.

Parts:

544' insulated #14 AWG Flex-weave wire
12 pulleys
#16 AWG copperweld ladder line
WA1FFL ladder lock

The shape of the loop is very nearly square. The run on the south and east side is slightly longer than the other sides by about 3 feet, all sides except the northwest corner are 30 feet high, the northwest corner is about 15 feet high (no tall trees unfortunately). The feedpoint uses a WA1FFL ladder lock which is the only way to do this if you ask me. Way more easier than drilling holes in sheets of lucite, etc.

I have a Dentron Super Super Tuner (AT-3K) that does a nice job of matching to the rig.

It's a shame that loops don't get any more attention than they do - it's the best wire antenna i've ever used. I don't really have any intention of pursuing a yagi now...

thanks!

hi,

Mine's up 30 feet except one corner. Its receive performance is as good as my inverted vees without a doubt. I haven't had a chance to test the TX performance however I am able to work places in the US that I never have before with the dipoles. The places where I have worked before seem to give me better reports.

I don't know how much i'd worry about the loop being resonant - if you have a strong enough tuner i'd put up as much wire as you can as circular as you can and let the tuner take care of things. I know that's an unscientific approach but there are plenty of guys on this list with loops that are nowhere near any resonance point that are having great results. The weak link in the chain appears to be the balun - my 3KW Dentron tuner has a balun inside of it that may be put under stress trying to match a strange impedance at 1500W RTTY but I don't have that kind of amp here.

I'd say the most important parts of the loop are the length, the feed line (preferably ladder line) and height. A loop with all sides at nearly the same height seems to perform better than a loop with high and low points based on the experiences of others on this list.

hope this helps.

Jason:

I think that's a capital idea! Since we are so far-flung, we might
consider 20 meters SSB daytime or 40 at night. Roundtables are hard
to manage on CW but I'm game for that, too.

My weekends are typically not my own but I should be able to steal some time late Saturday or Sunday afternoons...2100Z to 0000Z. Jason, you started this thing. You want to pick a frequency and time and let's see who shows up?

I think a Sky Wire site would be great! I'm sick of all the antenna sites that are full of dead links. I'd like to see a site that hosts the information itself, rather than solely providing a bunch of links.

Well, I was going to offer to register and host skywires.net, but it looks like someone already has .com and .net. Neither one even works. All I get is "Access Forbidden". :(

1950. tuner question

Yahoo group: SkyWires
Date: 2006-11-19 15:26:25 UTC
From: Jason Buchanan
Topic: 1950 Message: 1950

hi,

Quick tuner question...

I've noticed that with this Dentron tuner I can tune to a given band in a few ways.

For example, on 20 meters, I can tune the SWR to 1.0:1 using the A, B or C position but the more inductance I add the sharper the peak is and more critical I tune carefully. On the A position I can be off +/- .5 on the antenna or transmitter controls but on the C position it has to be exactly right on target to get the SWR low, there's no room for slop.

The main question I have is How much stress am I putting on the tuner by using the least inductance (position A) vs. rotating the inductance knob CW (position C) and running with 1 KW? The receive performance seems to be the same although I guess you could say that as I increase the inductance i'm narrowing the peak of the passband.

I don't want to stress the tuner components/coils by running high power and not using the right amount of inductance, etc.

Thanks,
Jason

All other things being equal, the best efficiency comes from using the smallest amount of inductance. Coils are where you'll have your greatest loss (via heat generation). That is why most people use the smallest amount of coil given otherwise equivalent tuning solutions.

The sharper tuning is a result of greater efficency, better Q, and all that stuff. As you note, you are seeing the 'bandpass' or 'bandwidth' changing at the various settings.

Provided you are operating within the design parameters of the transmatch I'd not be concerned about damaging it. Just be aware of how far you can traverse from the original tuning point before you need to re-tune and use your judgement for ease of operation vs. greater efficiency.

I'd expect the broader tuning is putting more stress upon the transmatch because it is operating with less efficency and therefore is dissipating more power inside its components. But even if this is true, that is not the same thing as saying you are operating outside the transmatches designed parameters.

If you are really worried about it, measure your impedance and voltage at the various tuning solutions and compare this to the transmatches design parameters.

Sounds good - well that's kinda where it gets confusing because the Dentron tuner appears to have the least use of the coil on the A, B. etc. position, where the Q and R position use almost all of it.

> I'd expect the broader tuning is putting more stress upon the transmatch
> because it is operating with less efficency and therefore is dissipating

I'm careful to tune the SWR to near 1.0:1 before cranking up the power. But i'm just not sure if position A (least coil) is preferable over position C (more coil) with SWR at 1:1 in terms of long-term component life.

It's a real big job to get inside the tuner so before I spend 15 minutes opening it up I thought i'd ask the list here for their advice hi

Thanks,
Jason

The next time you open it, also verify the capacitor knob(s) is(are) properly lined up. You'll want the marks on the transmatch face to be accurately indicate the caps position, and note which end signifies fully open and which end signifies fully meshed.

While you're at it look for any scorch marks (black burnt looking areas). If you see any, it has likely been arced at some point. Too much voltage caused a spark to jump from one point to another inside the transmatch. This doesn't always cause damage but it is never a good condition for the transmatch to operate under.

> I'm careful to tune the SWR to near 1.0:1 before cranking up the power.

Yes, extremely wise!

> But i'm just not sure if position A (least coil) is preferable over
> position C (more coil) with SWR at 1:1 in terms of long-term component
> life.

Theoretically position A (min. coil) is better.

From a real-world practical point of view if you are getting a 1.1:1 swr at both settings I can't imagine it makes any difference to the receiving station at all. There simply is not much mismatch in either case, so I'd expect the party with whom you are communicating will never hear any difference between the two 1.1:1 swr settings.

If the transmatch gets overly warm then I'd worry. Since you are running fairly high power you need to be aware of small changes which may indicate a potential problem is brewing. It's always better to catch trouble before the smoke gets out!

That is the only practical reason I'd consider always running the minimum coil even at equal swr. Greater efficiency will result in less heat dissipating inside the transmatch by its components.

However, also remember most amateur radio equipment can't measure accurately with great precision. Obviously it depends upon the components used by the manufacturer, but I've always heard a 5% to 10% margin of error is considered good for amateur radio gear at HF, and it tends to rise at UHF/VHF, unless special care and attention is given. Inaccuracy also tends to rise with the cheapo knock-off brands; when they use inferior components they get inferior results.

Perhaps someone else that has experience with Dentron equipment can chip in here and let us all know what level of accuracy they've noted with their Dentron gear. I have no idea, but I've always heard it is good quality equipment, so I'd expect it to be pretty accurate, meaning closer to the 5% error. But that is just me guessing.

Hi Jason,

My rule of thumb has always been to start with the lowest inductance. It is a bit more awkward with switched inductance than a Rotary inductor. I connect the antenna to the tuner and the tuner to my xcvr via a noise bridge (be sure you don't transmit into the noise bridge!). I then adjust the rotary inductor from the minimum direction and adjust the capacitors until i reach a satisfactory match. I write down the inductor settings (an old WWII surplus unit) and then put the noise bridge away and use the swr meter to do the adjustments when operating.

I like to set the inductor to the minimum value that will allow the capacitors to handle adjustments on the particular sections of the band that I use.

1958. loop resonance

Yahoo group: SkyWires
Date: 2006-11-23 16:09:02 UTC
From: Jason Buchanan
Topic: 1958 Message: 1958

hi,

Well it seems that having a 544' loop works well for 160, 80, 40 and 20 but above 20 the feedline seems to become the radiator, or at my QTH anyway. I can't match to the loop on 15 meters as the loop is resonant at 22.170MHz with 544' of wire.

If I lengthen the loop to around 560' for better resonance on 20, 15, etc. this would put the loop resonant at around 1.79MHz. How badly does this screw up operation on 160 meters? I guess this is more a function of the tuner and its ability to match those impedances... but I was wondering if anyone did the same and how their 160m operation was affected?

and I guess the other question is whether or not it is worth it to do this... how well does a 560' loop work on 15, 12 and 10 meters?

Thanks!

Jason, remind me: how are you feeding your loop? As mentioned before, mine is electrically short for a full wavelength on 160 (it's about 470 feet...that's just how much wire I had and room to string it up), it's really too low to the ground, but it works fine on most of 160, 75/80, 40, 30, 17, 15 and 12. My MFJ autotuner won't match it on 10, but I think that's more a factor of the method I use to bring the open line into the shack past six runs of coax, a ground strap, water pipes, etc. I use 450-ohm window line to the center conductors of a 20-foot-long run of two pieces of coax taped together, and with their shields shorted on each end.

The only balun in the mix is the 4:1 current balun at the balanced input in the tuner. I can unshort the coax shields on the window-line end of the two coax cables and load fine on 10, but then I lose 75 and a portion of 160.

I'm delighted with my skywire! I've gotten downright evangelical about the silly thing! It's low to the ground...no higher than 35 feet and as low as 15 feet...but it seems to work wonderfully. I worked 5A7A (Libya) last night on 75 SSB, breaking through the pileup on the third call. Got him on the first call on 30 CW the other night. And that's with 100 powerful, pulsating watts!

That's a long way to say that if you are feeding with ladder line, you shouldn't have to worry about resonance.

Still like to try to get some of us skywire guys together on the air sometime so we can compare notes. I'm free off and on today, all day Friday, and all day Sunday. don@... or n4kc@....

1960. Re: [SkyWires] Re: loop resonance

Yahoo group: SkyWires
Date: 2006-11-23 20:39:20 UTC
From: Jason Buchanan
Topic: 1958 Message: 1960

> Jason, remind me: how are you feeding your loop?

hi - i've got somewhere around 90 feet of #16 ladder line that makes a few twists and turns from the shack, through the garage and out the window up to the roof line and then about 30 feet horizontal to the feed point. That's the best I could do due to the layout of the house. The shack is in the middle part of the house in the room next to the 2 car garage.

The loop itself is about 25' high in all places, some places closer to 35' but mostly 25' with the NW corner at around 15' (no tall trees).

The Dentron 3KW super super duper tuner does a good job of tuning pretty much everything to 1:1 except for 30 meters which won't tune when feeding my rig from the tuner through the amplifier to the rig. If I go direct from the tuner to the rig it is fine. Weird.

160, 80, 40 and 20 work and tune fine but 17 never goes below 1.5:1 and 15 causes everything in the shack to pulsate and hum when I key down; I am pretty well convinced that the ladder line itself is what is being tuned and radiating. My thoughts were that because the 544' of wire is resonant at 22.169MHz the tuner finds the feed line more attractive than the loop. I have 20 feet of unshielded wire that i'm thinking about adding on Saturday which would bring the loop in resonance on 15 meters around 21.382MHz and more reasonable for the tuner to work with. I'm not sure if this would really help - I hate to screw up 160 meters when there's more action there for me than 15 meters right now.

I worked 5A7A 3 times in the last few days on 160 meters (quite effortlessly I might add). The first time I didn't appear in the log so I worked 5A7A last night 2 times 5 minutes apart just to make certain that I made it to their log! hi The antenna is definitely a force to be reckoned with despite being so low to the ground. I think i'm lucky in that I have a lobe in their direction but I haven't worked enough with the new antenna yet to derive a pattern. Life and work are getting in the way hi

Its performance on 80 meters is excellent but I haven't had enough time to put it through its paces on 40. On 20 meters it's a toss-up between my vee at 40 feet and the loop in terms of QSB, etc. The signal is about the same but when QSB hits the 20m vee the loop is relatively unaffected - only when the remote station is suffering QSB do I notice it at the same time on both antennas (remote's greyline times). Otherwise QSB is greatly reduced and noise is a few dB less, too.

> Still like to try to get some of us skywire guys together on the air
> sometime so we can compare notes. I'm free off and on today, all day
> Friday, and all day Sunday. don@... or n4kc@....

Friday's sort of a wash for me but Sunday may work. There is another contest going on this weekend so while I may not be in the contest I will try to figure out where I'm hearing and try to figure out what the loop's pattern is. May be hard to determine this if the California kilowatt stations are ionizing the air hi

A goof on my part. I've verified it a few different ways and the SWR is
1:1. Picked up a bunch of new DX today on 30 meters.

Working DX on 40 meters is like scooping minnows out of a tank.

I have noticed that the radiation pattern is very much like the side-fed
pattern on L.B. Cebik's page at http://www.cebik.com/wire/hl.html when
comparing my 40m vee vs. the loop.

From: Don Keith
Topic: 1958 Message: 1965

Hal, I do! Yes, it is a good, practical, well-written article. Lord knows, we need as many of those as we can get! Hope you'll do more.

I've come late to the ladder line/window line camp as I was always lured to the ease of use of coax. I've seen the light...and it's thru those little rectangular holes in my 450-ohm window line. But I may well use your method to make a short run of open line for a ten meter vertical loop I now have fed with coax. I'd like to try it on 6 meters.

73,

Don N4KC

You can use other things for the spacers besides pvc pipe. I just happen to have that on hand. Someone suggested using plastic clothes hangers, as that would be lighter the the pipe.
Just remember its the spacing between the wires that is important.

1967. RF going back to station

Yahoo group: SkyWires
Date: 2006-11-29 15:01:56 UTC
From: Bostjan Voncina - S55O
Topic: 1967 Message: 1967

Hellow!

I have some problems with Rf with my loop. Should i put a 1:1 balun on the cable to the antenna, to choke the RF coming back to the station ?

The loop is a 80m hor. loop with 400 ohm open wire feed.

Thank you

Bostjan S55O

1969. Fw: [DX1MK] drawing of 40m delta loop

Yahoo group: SkyWires
Date: 2006-12-01 02:00:27 UTC
From: cesar maligalig
Topic: 1969 Message: 1969
Attachments: 1 described; binary payloads are missing from this source WARC

Dear All,

I have successfully built a 40m delta loop, after hoisting it up and down for about ten times! Attached is a very poor drawing, any suggestion for a better software that MS Paint. The loop is slanting to about 45 degrees down to the lower corners. It is attached to a pulley tied to a coconut tree, and used 12" bungee cord on the 2 lower corners. I removed the 1:1 balun and replaced it with a homebrewed center connector. Please don't hesitate to ask about construction and tuning. I tuned it with my Vectronics manual antenna tuner - no antenna analyser - can't afford one! hihihi

1971. polarity

Yahoo group: SkyWires
Date: 2006-12-09 20:27:16 UTC
From: Jason Buchanan
Topic: 1971 Message: 1971

hi,

Just wondering if it was typical to alter the pattern of the loop by changing the polarity of the ladder line? Seems like I can hear well east/west with the polarity one way, and then more favorable to the north/south when I switch the polarity around.

I've done some rough testing on 20 meters using a DPDT 125V toggle switch and can produce consistent results to favor east/west or north/south by changing the polarity going to the tuner.

My loop is nearly square, the feedpoint is along the southern side about 2/3rds to the right.

I am on the prowl for a nice ceramic DPDT knife switch if anyone has a spare.

thanks

Jason
I've noticed a similar phenomena, though my loop isn't square so there's not much science to be done at my place... I am hoping one of the rocket scientists among us will weigh in on your question. For me, I hear about the same no matter what the polarity, but on transmit I see the effect pretty clearly. I am typically running low power (sub 10 watts on CW) so every little thing helps.

Hello,
You may find this "freebie" drawing program helpful:
http://www.cs.uu.nl/~markov/kids/draw.html

I use it for all my antenna construction projects. Very simple program but after you get used to using it most helpful to say the least.
Good luck and 73,
Wayne

sounds good - well from what I've tested so far it makes a pretty big
difference for receive sometimes when I flip the polarity... 20 meters
anyway... I haven't had enough time to compare on the lower bands.

Wayne,

Thanks for the info. Right now I have installed my delta loop tied to 3 coconut trees with two bungee cords on the two corners across the feedpoint. Though I could not achieve the 1.1:1 swr anymore, I am happy with the present 1.4:1 swr. 73

1979. New member,loop vs dipole question

Yahoo group: SkyWires
Date: 2006-12-18 04:46:54 UTC
From: Mike
Topic: 1979 Message: 1979

Hi all, Looks like I may give the hobby a try again. I gave up after years of trying to copy code with no luck. I got so aggrivated I haven't even been on VHF/UHF in over a year. Anyway, I have a 160-10m Doublet (Dipole - 240ft) with 100ft of 600 OHM feedline I got from W7FG a few years ago that I never put up.I have a few trees but most are only around 20ft high. If I were to string up the dipole it would run NW to SE because of the tree locations.I've read a little about the loops and have a few questions. I'm thinking I could add another 388ft+/- to the dipole I have to make the loop.It would be more of a triangle shape with the longest leg running north to south. Would the loop work better than the dipole at the low height? What about maybe getting 30ft high by using some PVC pipe against the trees for support? Would 10 ft higher make much difference? My HF equipment consist of a Kenwood TS-850, Yaesu FT-990, Johnson "Match Box" & Ameritron ATR-30 Tuners and a Heathkit SB-1000 amplifier. Thanks for any suggestions, Mike

Mike, I run a short 1 wavelength 40 meter loop at 20 foot and a longer 1 wave 160 loop at 50 feet high. They both work well for US and some DX contacts. I am building a 80 meter loop for a friend and it will be supported by four 30 foot plastic pipe masts and 450 ladder line feed. I tried it out here and it worked very well 40 and up and OK on 80- contacts 300 to 1500 miles with good reports on the 100 watts.

Healthfully yours,
Don W4BWS

1983. New with 2 MT mobile ant question

Yahoo group: SkyWires
Date: 2006-12-18 16:33:38 UTC
From: Carol
Topic: 1983 Message: 1983

Hi group. My husband has a geo metro (chevy metro actually) and he is looking to put a 2 MT mobile antenna on it. As there is NO room between the rooftop and the head liner, he is thinking that a 5/8's ant is out of the question. My personal experience has been that 5/8's work better than anything else. The car is pretty small. Any suggestions for an antenna? Thanks, Carol B (KJ6OC)

He's concerned with scratching the roof. I suggested putting a wash cloth under it. Then there's the problem of having to run the coax through an open window in the rain. On my car, he drilled a hole and ran the coax through the liner. There's no room to do that on the geo without the possibity of someone hitting there head on the connectors. He has thought of using a round ashtray from one of our parts cars (long story LOL) to cover over it. He just thought there might be a better idea or another place to put the antenna besides the roof. I'll pass this along to him. THANKS, Carol (KJ6OC)
P.S. Tell me about 1/4 wave antennas. Have you had good reception with them? We tried a through the glass one years ago and I was very UNIMPRESSED with the reception.

Mike,
The very very best thing about loops is that you can throw up a few versions in a single day and try them all out before you decide which one you like best. My antenna here evolved from an end fed Zepp to what I called a Zeppalooper - sort of a folded doublet that was triangular in shape though electrically a double Zepp. Both these antennae worked. Once I sorta-squared the triangle by figuring out how to throw a support line over a bendy white pine in the yard, I had a 40m Skywire Loop. The whole thing is about 15' high on average over level ground, fed at one corner with 300 ohm TV twinlead. Works wonderfully - not unheard of for me to work phone to Brazil with 30 watts or Europe on CW with 5 watts. Strangely, this CHEAP antenna (all told, about $12) busts through pileups and makes my little bitty signal sound huge.

Being one of the few non-scientists on the list (I'm a corporate spook) I am not able to make a credible stab at the mathematics to explain how it all works - the great thing about antennas is that you can get out and try stuff to see what works best.

The SB-1000? You might find you can get away without it.

Have a great evening,
73,
Jim

Subject: [SkyWires] New member,loop vs dipole question

Hi all, Looks like I may give the hobby a try again. I gave up after years of trying to copy code with no luck. I got so aggrivated I haven't even been on VHF/UHF in over a year. Anyway, I have a 160-10m Doublet (Dipole - 240ft) with 100ft of 600 OHM feedline I got from W7FG a few years ago that I never put up.I have a few trees but most are only around 20ft high. If I were to string up the dipole it would run NW to SE because of the tree locations.I've read a little about the loops and have a few questions. I'm thinking I could add another 388ft+/- to the dipole I have to make the loop.It would be more of a triangle shape with the longest leg running north to south. Would the loop work better than the dipole at the low height? What about maybe getting 30ft high by using some PVC pipe against the trees for support? Would 10 ft higher make much difference? My HF equipment consist of a Kenwood TS-850, Yaesu FT-990, Johnson "Match Box" & Ameritron ATR-30 Tuners and a Heathkit SB-1000 amplifier. Thanks for any suggestions,
Mike

NEVER use a thru the glass antenna. Pure crap! haha! If you are in an area with repeaters all around on towers or high buildings,the 1/4 wave is the way to go because they propogate upward more quickly. 5/8 wave are flatter to the ground for longer simplex coverage or hitting a repeater that is out there a ways.
Listen, the are all kinds of antenna mounts these days. Trunk lip mounts, bumper mounts, etc. Look around on the net and you'll likely find something you can live with.
Heck,I found a wife there once! hahahaha! Now with our mag mounts, coax runs thru trunk deck lip or the truck door on passenger side and is never moved. Cut a piece of clear plastic like drop cloth or something for under the mount. Keep it clean and waxed under there and no problemo grande.

I've had good luck with ? wave 2m mag mounts here in mountain country.
But if you're worried about scratching paint, you need to remove the mag
mount regularly and clean under it. No matter what, at least here in AZ,
dust will collect under that magnet, and eat the paint like sand paper.
Also, I've gotten along fine running the coax past the rubber seal
around the door, rather than out the window. But that said, just pull
the mag mount off when you park, stick it inside the car, and put it out
again when you're ready to drive again.

Thanks Much to everyone. I'll pass this along. He came up with another idea tonight. Will let you know what he does when he gets around to it. LOL Probably after Christmas. Carol (KJ6OC)

P.S. He is blessed with a wife (35 years) who LOVES ham radio (even though we haven't been active in recent years (another story) among other things. LOL He's currently cleaning up my old Hallecrafters (first HF rig) which has been in storage so I can get back to at least listening. Espeically to CW my first love. LOL

1993. Introduction...

Yahoo group: SkyWires
Date: 2006-12-19 07:18:28 UTC
From: n6vl
Topic: 1993 Message: 1993

Hi,

I am new to this group.

Here is my current situation. I have a pseudo-horizontal delta loop. It is a tilted delta loop with about 225 foot of wire with the apex at 40 and the lower corners at 6 feet or so. It is based on a design by Doug DeMaw, W1FB. It is described in one of the ARRL Wire Antenna Classics volumes. His version was a full size 1 wave length on 80 meters while mine is about 80% of full size. The lower horizontal side is about 80 feet long. The other two sides hang a drooping 45 degrees from the apex. Per Doug's article, I feed it at a lower corner with REAL 450 ohm ladder line. I found some old line at a swap meet with 1 inch spacers every 6 inches. This was before the days of windowed ladder line. Oh yes, I feed it with the 275 watt Johnson Matchbox. I take Cebik's preference for link coupled tuners seriously.

So here is my dilemma. I live on a typical Southern California postage stamp lot. It is 60 by 100 feet, with 60 by 80 really being usable. The lower corner feed lowers the angle of radiation some and I have had good luck working into the midwest on 80 from the west coast. It seems to be a good all around antenna on 40 comparing favorably with a GAP vertical in many comparisons. On 20 it generally hears better than the vertical, though EZNEC does not show it be a real low angle radiator. On 17 and above, the vertical is almost always a better on receive and I don't even try the loop.

I would like to have a smaller purely horizontal loop for the higher HF bands. Yet I don't want get rid of tilted delta loop for the lower bands. I only have so many options on my lot. I have considered a 40 meter loop since a larger one does not really help on higher bands. A recent QST article says to limit a horizontal loop to 5 wave lengths at the highest frequency. But is is hard to mount it and keep my current delta loop.

I am also considering a loop only 28 feet on each side. I have four SD-20 fish pole blanks from World Radio magazine. They are each 20 foot long. They could be mounted on central hub 90 degrees apart. The distance from the end of each pole is 28 feet. The resonant frequency would be 8.8 MHz. This way only one support is needed. Again the problem is finding room.

I could take my 225 feet of wire (or similar length) and make it all horizontal. The problem is the cloud warmer effect on 80 and 40. Also I would need to find 4 high supports. I have one 40 foot support and don't want to alarm the neighbors further.

Has anyone had experience with two loops very close to each other/ Any other suggestions are welcome.

> Does your tuning change when reversing the polarity? Just curious.

hi - yes - the SWR is a little higher when reversing the polarity - if I tune to 1:1 with the tuner and then reverse the polarity the SWR may be 1.1:1 depending on the band, but never more than 1.15:1.

But there is a tremendous difference when changing polarity it seems - especially when the conditions were poor last weekend I could change polarity and I would see a 3 S unit difference mostly due to an elimination of multipath. On modes like WinDRM or AOR where there is 2.5KHz of wide digital signal I can see where the multipath is greatly reduced from one station to the next. The only problem was I was having to stand up in front of the switch most of the time flipping the switch as I would go from one station to the other... and as the propagation varied sometimes I would switch back in the opposite direction... and then some guys were better on the little 20 meter dipole...

Based on these experiences, i've formed the opinion that the length of a wire antenna and its placement appears to be the main benefit to the loop because the cancellation of signals is reduced with the greater capture area of the loop, compared to the smaller surface area of the dipole which can capture only 1/4 wavelength on the center conductor.

Now if I could just figure out a way to put up a loop around my property that is 320 meters long! hi

Jason,

Thanks!

Did you ever find a ceramic DPDT knife switch? I sure would like to find one. I think a knife switch would also better preserve the balance since is like shaped like balanced line. I don't think a ganged pair of ceramic wafer switches would be a problem either.

Check out the W5DXP page at http://www.qsl.net/w5dxp/notuner.htm. Cecil is using DPDT knife switches to change the feedline length. His don't seem to be ceramic. I wonder where he got them.

Are you transmitting on WinDRM or just listening? I think you can transmit with an SDR-1000 rig. I know a ham locally who has an AOR unit, but I never asked him about it. I am on a CW kick at the moment, but not that good at it.

If you don't want to drill a hole in the roof because the headliner
is too close, and are concerned about rain coming in around the coax
on a mag mount, why don't you try one of the thru-glass mounts?

One example is the Larsen KG144UDPL

I found some on ebay off and on. There's actually quite a few of them so if you see one that looks cruddy and would rather wait for one that looks better, just wait. Search for knife switch and ignore all the switchblades.

I just bought one which should be here in a few days. Figure on spending $25 for one in good condition.

> Check out the W5DXP page at http://www.qsl.net/w5dxp/notuner.htm.

The ones that W5DXP is using look like the Philmore brand that are about $5 each. Made out of plastic with nickel plate on the switch itself. I could be wrong but that's what they look like. Probably just as good but I envision myself needing only 2 switches so i'm going to go for the old ceramic ones. That's a good page though as i'm going to do some fiddle-faddling with the polarity and feedline length to tune the bands higher than 20 meters.

There's a big WinDRM net on Saturday and Sunday at 2000UTC at 14.236 USB. AOR Net is at 1900UTC. I'm usually at both except for the coming weekends (family coming into town). There's an AOR contest to win a new AOR 9000 - check out http://www.hamradio-dv.org/aor/digital-ssb/special-events/hello-dv-contest.htm for more details.

hope this helps!

cul Jason

My uncle Mel K0PFX uses his SDR-1000 with the AOR and WinDRM, and CW too!

I spend the majority of my time on CW but AOR and WinDRM during the day
on the weekends - 14.236 USB.

Now that i've got the loop up I can always find a band to use regardless
of solar conditions.

2003. Re: [SkyWires] New with 2 MT mobile ant question

Yahoo group: SkyWires
Date: 2006-12-20 15:47:51 UTC
From: Andy
Topic: 1983 Message: 2003

Hmm, kind of off-topic for Skywires....

We used magmount 2 meter antennas for a few years with no problem, no scratching that I could see (except when some idiot tries to move it by dragging). Did notice the circle after the thing had been in place for a very long time (less oxidizing under the magmount), but it soon disappeared. But I'm in the northeast USA where dry sand doesn't happen.

We ran the coax in along the rubber door seal, not through the window. No leaks. Just quick-and-dirty. Yes it squashes the cable a bit, but in our minivan there was almost no compression. We did have problems with the connector on the end of the cable, but not with the cable itself.

I have read that there's very little practical difference between 1/4's and 5/8's in actual use, when center-mounted on a vehicle roof. Yes, I understand the theoretical differences (even studied them in college, starting with Maxwell's equations). But people have made measurements looking for differences and finding not much if any difference when you come down to it on top of a typical car roof or trunk. It's only a couple dB difference anyway, if there were one.

A through-the-window-mount antenna is crummy because it's so far off-center and doesn't work against a groundplane, among other things.

Andy

Thanks Andy. I knew it was off topic but we read about this group and figured maybe we could get away with it. :-) His car is small enough that a 5/8 is ok. It was just a matter of where to run the coax etc. We like the idea of drilling the hole and making it permanent. That way we don't have to keep messing with it. I think he mentioned the possibility of running along the door seal. He tells me he thinks he's figured out what he wants to do. Thanks for all the suggestions. Carol (KJ6OC)

>A through-the-window-mount antenna is crummy because it's so far off-center
>and doesn't work against a groundplane, among other things.

Since this was brought up, and in fairness to
Larsen, they do disclose all potential
installation problems up front in their online
literature. I've pasted in the appropriate sections below.

Additionally, their glass mount antenna only has
0.5 dB loss compared to a hole-mount 1/4 wave
mounted in the center of the roof. A center of
the roof mag mount has 0.2 dB loss. So the loss is essentially insignificant.

The glass mount antenna is a half wavelength. Does it need a ground plane?

From Larsen:

Q. I moved my on-glass antenna from my old car to
a new one. It worked great on the old car, but I
have a very high VSWR on my new car? Why?

A. Your new car probably has passivated glass ---
glass impregnated with tiny metal particles which
render the glass incapable of coupling RF between
the inside and outside couplers.

Q.How can I tell if the glass on my vehicle is
suitable for one of Radiall/Larsen□s on-glass antennas?

A. First, look near a corner of a window for
words meaning or relating to "sun" or referring
to ultraviolet or other forms of radiation. If
you find terms like "Soft-Ray", "EZE-Cool",
"Solar-Coat", "Solar-Cool", "Insta-Clear" your
glass is probably passivated and won□t work with
on-glass antennas. If you don't find these
helpful words on the glass and want to be 100%
certain, ask a 2-way or cellular shop technician
to test your glass with a capacitance meter.

Q: I purchased one of your KG series through
glass mount antennas, specifically one for VHF
144-146 MHz. I installed the antenna according to
your directions, and have obtained an SWR of
1.5:1. But, the antenna is "deaf", it receives
poorly. I have tried another transceiver and
changed the UHF connector on the fixed coax end,

and my results are the same. Is there something I can do to make it work better?

A. Many factors can affect the performance of on-glass antennas. These include:
Glass Thickness: KGs are designed for glass with a typical thickness of .0151 ± .002". Anything greater or less will result in a frequency shift. Most automobile manufacturers have side and rear glass panels within this tolerance. If the mounting surface is thicker or thinner, this value will change the dielectric constant and change the resonant frequency of the antenna.

Height on glass: The lower on the glass the antenna is placed, the greater the reflection from the roof. This will cause the VSWR to increase.

Tint: Various tints affect the dielectric constant causing a higher VSWR, poor reception or no performance.

Dielectric Constant: The couplers (inside / outside) function as a capacitor. The distance and glass material content between these two plates affects the capacitive value. If you are using a Radiall/Larsen GT Coupler (a glass tester for capacitive values), the galss may not exceed 3 pF of capacitance. Anything greater than 3 pF and FR will not pass through the glass.

UV Glass: Many newer vehicles are manufactured with UV resistant or passivated glass containing metal flakes which destroy the capacitive function. One way to tell if your vehicle has passivated glass is to look in the window for the manufacturers' stamp. If the brand has the word SOLAR in it, the glass is not adaptable for RF purposes.

Q: I finally saved enough to buy my first new car! What type of antenna can I buy that won't require drilling a hole in the car?

A: Glass mount antennas are easy to install and do not require drilling a hole. Just be sure the antenna is mounted high up on the glass and not over defogger wires or on reflective window tint as this could impede performance.

Q:Does the black paint around the edge of the window reduce antenna performance?

A: No. The black mast paint used around the
perimeter of the rear window glass on domestic
vehicles has not been shown to be detrimental to
the glass mount installation. The only difficulty
in this preferred installation is the inside to
outside alignment of the coupling box to base foot.

Q:Does it make a difference if I mount the
antenna on a corner of the window instead of the center of the glass?

A: The best location is near the center of the
roofline. If the installation required mounting
to the corner, there should not be significant
performance degradation. Always install the
antenna as high on the glass as possible.

Q:Does it make a difference if the antenna is
mounted on the front or back window?

A: Glass mount antennas are designed for tempered
automobile glass with a nominal thickness of
5/32". Front windshield glass is a laminated
safety glass, which is thicker and causes some
degradation to the VSWR match. Expect a VSWR match to be nominally 2:1.

Q:Can I put a glass mount antenna on glass treated with Rain-X?

A: No. Chemical properties of Rain-X reduce the
holding ability of the adhesive tape used on
glass mount antennas by over 50%. If Rain-X or
another acidified alcohol surface treatment has
been applied to the glass, it must be removed
from the mounting area. Try Bon Ami cleanser or
Ultra Brite fluoride toothpaste.

Q:Any quick tips for installing "on-glass" antennas?

A:Remember:
* Install only on INSIDE of window.
* Do not mount antenna on any dark tinted
area or on an area where an after market tinting film has been applied.
* Do not install over in-glass AM/FM dipole antenna.
* Do not install on glass with metallic
content (passivated glass i.e. "solar-coat", "solar-cool").
* If possible, avoid installing antenna on curved glass.
* Clean inside mounting area with alcohol pad
provided in the installation kit. Wipe off excess
alcohol. Do not allow alcohol to dry on the
glass. If window film is apparent, use a mildly
abrasive detergent-type cleanser. Do not use
ammonia-based or similar type of glass cleaner.
* Vehicle glass should be near room
temperature (70° F / 21° C) prior to installation

and remain at this temperature for 3 days
following installation for maximum antenna-to-glass bond strength.
Here's what some hams said about the glass
mounts: http://www.eham.net/reviews/detail/1062

I don't own one and have no connection to
Larsen. I do know hams that use this antenna and
all tell me that they can't tell any difference
between it and a 1/4 wave mag mount on the center of the roof.

Some other things to watch out for with glass-mount antennas:

1. Avoid the shortened ones (usually with a coil in the middle) that are made to look like car-phone antennas.

2. Tinted glass may have conductive material in it, as the previous reply says.

3. Watch out for embedded wires for defroster, or for the AM/FM antenna. I've been told some AM/FM antenna wires are so fine you can barely see them.

If it's a halfwave antenna, I think you're right, it shouldn't need a ground plane. Regardless, the presence of the roof, to one side (and only one side) of any antenna, will affect its radiation pattern somewhat.

Many window-mount antennas I recall seeing were short, much less than 1/2 wave, probably even shorter than 1/4 wave.

You can also get through-the-window couplers without antenna, that you can use with a center-mounted antenna to bring the signal in without cutting holes or running the coax along a door seal. They are more rare, but I've heard of them.

Jason,

This is off topic, but here goes:

Is there way to do WinDRM without an SDR-1000 rig? I have one that needs a simple repair and do need to get it back to Flex soon. I also have an ICOM 756 Pro 2. Not sure if I can get that rig to do WinDRM. What are you using?

Did something similar years ago with a TV twinlead from an antenna.
Didn't want to drill thru the walls in my new house, so I glued 2" diam.
copper discs with a short machine screw soldered to the center on the
inside and outside of a window. I brought the twinlead down from the
antenna to the outside discs and took more twinlead from the inside
discs to the TV set connections. It worked as if the wires were
continuous. Wonder if one could interupt coax with capacitive connectors
like that on car windows?

2011. Ladder line length?

Yahoo group: SkyWires
Date: 2006-12-22 17:53:34 UTC
From: Mike
Topic: 2011 Message: 2011

I will be using 600 ohm ladder line to the 540ft.+/- loop. I can make a short run approx 20-25ft from the window and almost straight up to the loop. Would this be OK or should I try to route a longer run?

G'day Mike , It sounds like you have the perfect feed 25ft of ladder straight up sounds perfect. I believe you then have the opportunity should you want to & joint the twinlead leads together & feed your system with a godd ground & then have a vertical.

If you have ladderline running close to something else metallic, including another line, some twists can be useful to help maintain electrical balance (minimize differential mode coupling) between the ladderline and the something else.

Otherwise I don't think it does anything, electrically.

In the old days of open-wire telephone lines (like you might still see running along railroad track beds), each of the wire pairs is transposed (flipped) every so often, for the same reason. The multiconductor cables that replaced them, do the same thing, with each pair in the bundle having a calculated twist.

Andy

Someone told me years ago that the twisting of ladder line minimized
whipping around when the wind was strong.

I have also noticed twists on tie-down straps on large trucks. I
asked one trucker about that and he gave the same answer.

Hi,

Looking at old msgs and saw yours. radio-ware, davis-rf and thewireman are some sources of ladder-line. I want to put up a loop. and should be able to fit a 80m 2wl loop but want to get on 160 and not warm clouds. A 160m 2wl loop is around 1100'. How is your 1080 loop working out and how high is it? What do you have for 40-10 and why are you keeping it up rather than use the 1080' loop for all bands?

Tnx,

Mike

From: Don Keith
Topic: 556 Message: 2020

I would say any of the three outlets mentioned below would be a good source of ladder line via the web. I bought mine from The Wireman (http://thewireman.com) and thought the price to be reasonable and the quality excellent. I've also had good experiences ordering from Radioware, though not ladder line. They do sell it as low as 33 cents a foot.

W4RNL suggests that a 2-wavelength loop works better than 1-wavelength, but not necessarily enough better to justify it unless you have the wire, supports, and acreage to stick up over a thousand feet of wire. I didn't even have enough of any of that stuff for a full wavelength on 160, but with about 470 feet in a rough octagonal shape, I'm having a blast way down there. It doesn't want to load on the lower 50 khz or on 10 meters, but it works like a champ everywhere else in the HF spectrum. It's not that high, either--15 to 35 feet above ground--but I doubt I'll be working much DX on 160 with 100 watts. I do get good reports out to 350 to 400 miles at night.

After more than four decades of more-or-less active ham radio experience, I've just recently become downright evangelical about the big loop. And don't even get me started on open wire/ladder line as opposed to coax!

2023. More loop questions

Yahoo group: SkyWires
Date: 2006-12-27 16:28:00 UTC
From: Mike
Topic: 2023 Message: 2023

Hi,

After reading some of the archives I've decided to try the 540' 2wl 80m loop. I was considering a 2wl 160m loop because I want to work DX on 160 but it might be more trouble than it's worth. I may try a 135' center-fed L for 160m as per Cebik if the loop is not good on DX. I have a little more than an acre and my guess the trees top out at 60-80' so I should be able to get the loop up high but lots of limbs to snake the wire through.

Home Depot has lots of wire but the biggest role is 500'. Has anyone spliced more wire onto their loop using what method? I would think soldering the joint would not stand up to the strain. Maybe a Western Union splice?

Has anyone compared the 2wl 80m to say a 80 or 160m doublet? Have they experienced the nulls that Cebik talks about on the higher bands?

I read that window ladder line gets lossy when wet and changes tuning when wet and exposed to wind, ice, etc and true open-wire line is best. Has anyone experienced this problem? I'm considering W7FG's 600ohm open-wire line for the loop.

Tnx & 73,

Mike KA2FIR

2024. Re: [SkyWires] More loop questions

Topic: 2023 Message: 2024

I spliced the wire on my loop by doing the WE splice and wrap and then soldering the joint. coated it with Glyptol, wrapped it with Scotch 66 black tape and then put heat shrink tubing over it. Maybe over kill but I didn't want it to break, corrode, and oxidize. Mine is 80 full wave and I used 450 ohm line and #14 THHN insulated wire from Home Depot. I plan to make my own 600 ohm line as described in QST Dec 2006 Page 55. This will be for replacement of the ladder line. Wish I could train a squirrel to run the wire through the limbs of the trees.

Healthfully yours,
Don W4BWS

Adam
You can make your own open wire 600 ohm line and it will work for any folded dipole antenna or to feed other antennas. I can send a copy of the article from Dec 2006 QST if you provide your e-mail address. Yahoo will not take attachments.

Im sorry I cant advise on any ladder line - being in Australia my brother told me he can get some 450 ohm line in from the US at 60cents per foot (thats around US .47c/ft). I mean its near impossible to find black 300ohm TV twinlead here but I've managed to pickup a 200mtr roll of white TV twinlead for AU $35. Im just not sure how its going to go as the conductors are so tiny. Anyway good luck folks

In our close-to-the-Atlantic ocean climate, mechanical wire joints alone without soldering become intermittent quickly. I use the "western union" splice, solder, then cover it with fingernail polish, and after that dries, shrink tubing or the stretchy self adhesive electrical tape.

I won't dispute your experience. I haven't had that happen yet maybe because I have the overwraps that support the joint and reduce flexing of the splice-Don't know. Any way, when in Florida for 40+ years I had the copper corrode in joints unless they were soldered and covered. So I just repeat what has worked for me in the past-always eager to learn something new however.

Hi Don,
It has been my experience that if you solder the splice it will break after some time . I just wrap the 2 ends together very well .

I spliced the wire on my loop by doing the WE splice and wrap and then soldering the joint. coated it with Glyptol, wrapped it with Scotch 66 black tape and then put heat shrink tubing over it. Maybe over kill but I didn't want it to break, corrode, and oxidize. Mine is 80 full wave and I used 450 ohm line and #14 THHN insulated wire from Home Depot. I plan to make my own 600 ohm line as described in QST Dec 2006 Page 55. This will be for replacement of the ladder line. Wish I could train a squirrel to run the wire through the limbs of the trees.

Subject: [SkyWires] More loop questions

Hi,

After reading some of the archives I've decided to try the 540' 2wl
80m loop. I was considering a 2wl 160m loop because I want to work DX
on 160 but it might be more trouble than it's worth. I may try a 135'

center-fed L for 160m as per Cebik if the loop is not good on DX. I have a little more than an acre and my guess the trees top out at 60-80' so I should be able to get the loop up high but lots of limbs to snake the wire through.

Home Depot has lots of wire but the biggest role is 500'. Has anyone spliced more wire onto their loop using what method? I would think soldering the joint would not stand up to the strain. Maybe a Western Union splice?

Has anyone compared the 2wl 80m to say a 80 or 160m doublet? Have they experienced the nulls that Cebik talks about on the higher bands?

I read that window ladder line gets lossy when wet and changes tuning when wet and exposed to wind, ice, etc and true open-wire line is best. Has anyone experienced this problem? I'm considering W7FG's 600ohm open-wire line for the loop.

Tnx & 73,

Mike KA2FIR

Hi Don ,
Here in Indiana I was using insulated stranded 14 AWG copper wire . I tried soldering the splice and then leaving it bare at that point . The wire would always break at the soldered point after some time due to flexing. I won't argue with success.

Years ago when splicing wires on commercial aircraft (before Raychem environmental splices) we would use a but splice or WE splice & solder & shring tubing. Before shrinking the tubing we would fill it with BLACK silicone RTV. When the shrink tubing was shrunk it would force the rtv into all the voids of the splice.The black rtv doesnt have acetic acid in it so it wont corrode the splice. Look at some of the original underwing splices on an older 747, thats how Boeing did it back then.

2039. 160m 2wl loop suggestions

Yahoo group: SkyWires
Date: 2006-12-29 04:22:12 UTC
From: donkunst
Topic: 2039 Message: 2039

I have been doing research on a new antenna to put up and found your group.

I have the room to put up a 2 or 3 wl 160m loop in roughly a rectangular shape. I plan to use aluminum 14 ga un-insulated fencing wire,(1/4 mile spool for $35) feed with 450ohm ladderline. I hope to get it between 50 to 75 feet off the ground. The ladderline should be 25 to 50 feet long roughly straight up. I plan to use a plastic or plexi-glass tee for the connection plate and use two short sections of coax with the braids tied together to go through the wall. I plan to use a MFJ 941D antenna tuner.

I live in a little bit of a valley with a hill/mountain to the north about 700 ft in height that will be at a distance of 1,500 feet parallel to the antenna. It will also be suspended over a 400 by 150 foot pond.

1. Will the aluminum wire be strong enough?
2. Should I use the 1/4 mile or just 2 wl, 1,120 feet?
3. Is it worth it to go to 3wl if possible?
4. For 2 wl, what is the optimum length of ladderline?
5. How do I determine that?
6. Is 50 ft above the ground enough?
7. What is the optimum height above the ground?
8. Will I get any benefit to have the north side higher than the south to cant the antenna away from the mountainside?
9. Will the MFJ be adequate for this antenna with 100 to 150 watts?
10. Looking for any other comments or suggestions.

Thanks KB3HJS

sigh

you guys really need to read the Management instructions for the list.
Set the list to MODERATED.
NO ONE posts a message to the list until one of you approves it.
ALSO, set the polls, links, photos, files, etc to not allow members to post
to them. Members can read them but cannot put stuff in them.
etc...

all 15 or so of my cancer and patriot and shooting/reloading lists are set
this way. My 5,000 or so members have no problem with these rules. I have
been running elists since before ONELIST and this is the quickest way to stop
spam that there is. it just means that messages do not get posted as quickly
(moot for the digest people) and more work for the moderators/owners. You all
do have TWO listowners per list don't you???

Jed,

There is a simple way to get rid of the list spam. Require list applicants to answer an easy question that all hams would know. Spammers won't waste their time trying to research it to get into the group. This works on yahoo groups I have set up in the past. I floated this idea about 6 months ago, and although many of the list readers replied that they thought it was a great idea, the moderator couldn't be bothered, and said there is not enough spam for us to worry about it. It is a trivial amount of work to make the change, but I guess that's just too much.

73 and Happy New Year,
Kyle

I use Liquid Tape. Get it at any hardware store and just brush it on. I use it for connectors, solder joints, etc. No mechanical only joints here - don't trust them.

Remains semi-flexible and lasts for years. I usually put on two coats. Some of my wires have been up for 10 years and the stuff is still clinging tight.

That's because you read messages by going to the website. Those like me who get the messages via email, see all the spam. 43 in the last year, half a dozen in the last week or two. Not as bad as some, but the trend is toward increasing.

Instead of setting everyone to "Moderated," why not just make only new members Moderated until they post one real message? I think that's how most other lists handle it, and it works pretty well with far fewer headaches.

Andy

Andy and the group,
I am one of three moderators, we looked through ALL the settings a while back to see if we could do any or all of the good suggestions that have been made, but in the spam and/or new member department we CAN NOT set them to be moderated or approve the first few messages. It would be nice if we could. All we can do basically do is to clean up after the fact.

To answer a question from another member, this list only has one owner.

I'm afraid I don't understand.

Are you saying you can't find the options to change this, or that this group
is somehow set so that those moderator options have become unavailable?

Or that your policy is such that you won't moderate new members?

Under Posting options for Moderation, there should be three choices:
Unmoderated,
Moderated, or
New members.

Admittedly it's a pain to deal with already-subscribed members (with a group
as large as this one is), but it ought to effectively handle most if not all
new members, those who join for a day or a week just to post spam.

I'm no Yahoogroup expert, mind you ... but this doesn't sound right.

Not that Yahoo wouldn't do anything like that, of course; but why would they make some groups NOT have all of the controls that other groups do?

Have you tried discussing this with Yahoo support? Do they have an explanation for why this option is missing?

SPAM settings are on already by yahoo.
and yes you can change these settings, more or less

go to the webpage for the elist
down the left column to MANAGEMENT
then click on GROUP SETTINGS
then on MEMBERSHIP
then click on the (edit) at the end of MEMBERSHIP TYPE & WELCOME

if common sense does not help you figure this out, let me know

you can not set someone to moderated for n number of messages
you CAN set everyone NEW to moderated. Give them a short message telling
them you want to know WHY they want to join, their CALL SIGN, and the
state/county they live in. Tell them in the message that if you do not get
the reply to those questions in 12 hrs, you will deny their application to the
list. I use something similar to this for all 15 of my lists. once you
approve them, you then have to keep track of who has posted a couple of
righteous questions or not. THEN you can turn moderation off. All that is
too much trouble for my 1100 member lists so I just leave everyone moderated.
that stops a lot of flames or insults, etc....

oh, be sure to have the owner set the moderators so that they see applications
for new members and also, new message and new photos, new files requests.
I do all the new members as the owner. the mods do the messages, and so on.

now, in addition... you want to turn off attachments because that is the
fastest way to spread malware and viruses, etc... most intelligent and
cautious people will immediately sign off a list if attachments are allowed.

so, go to MANAGEMENT
then to GROUP SETTINGS > WEBTOOLS (edit)

go there and change most of those to moderator or owner access for posting,
changes, etc. It will allow the members to look at what is in FILES, PHOTOS,
etc Be SURE that members can NOT look at the membership lists. Moderators
and owners CAN.

if common sense does not handle setting these, let me know and I will help you. Again, I have been running elists since at least the early 90s and before that, fidonet and BBS groups, etc back into the early 80s

>To answer a question from another member, this list only has one owner.

you better hope that he does not die or turn up brain dead some morning then. you will have a list you can do nothing with.

the owner should choose someone he trusts if only his wife or ??? who can transfer the list to one of the moderators when bad things happen.

I'd stick with the copper wire if only for soldering purposes...

I have use aluminum but great care should be taken to keep all connections perfectly clean and free from oxidation on all joints... oxidation can cause serious rectification problems...

I have used both. I found the aluminum fatigued in the wind
quicker than the copper. It is easier to solder to. I had to
make loop in the ends of the aluminum and use lugs and
bolts and nuts to make a good connection to the aluminum.
SO, take your pick.I still want to try steel fence wire for a big loop.

Healthfully yours,

Galvanized electric fence wire: can be soldered to easily when still shiney and new. Cheap - $17 or so for a half mile of #17. I would suggest liquid tape over solder joints. Stuff lasts for years - I know from experience.

What loop formula do you use for galvanized steel wire, instead of
the usual 1005/f formula?

2065. Re: Galvanized electric fence wire

Not sure. It was when I was living in Virginia. The loop was cut for 75 meters. I fed it with coax and just trimmed for low SWR. Feed line was only 25 feet long - feed point was right over the shack. Used a tuner to do all bands - worked fine.

But - I once had a "G.E. engineer" from Lynchburg, VA tell me that it was impossible to use galvanized coated wire as an antenna. The galvanizaation was an RF insulator, everyone knew that. Not sure what college he went to, must have been different than mine.

==========
I have been doing research on a new antenna to put up and found your group.

I have the room to put up a 2 or 3 wl 160m loop in roughly a rectangular shape. I plan to use aluminum 14 ga un-insulated fencing wire,(1/4 mile spool for $35) feed with 450ohm ladderline. I hope to get it between 50 to 75 feet off the ground. The ladderline should be 25 to 50 feet long roughly straight up. I plan to use a plastic or plexi-glass tee for the connection plate and use two short sections of coax with the braids tied together to go through the wall. I plan to use a MFJ 941D antenna tuner.

I live in a little bit of a valley with a hill/mountain to the north about 700 ft in height that will be at a distance of 1,500 feet parallel to the antenna. It will also be suspended over a 400 by 150 foot pond.

1. Will the aluminum wire be strong enough?
2. Should I use the 1/4 mile or just 2 wl, 1,120 feet?
3. Is it worth it to go to 3wl if possible?
4. For 2 wl, what is the optimum length of ladderline?
5. How do I determine that?
6. Is 50 ft above the ground enough?
7. What is the optimum height above the ground?
8. Will I get any benefit to have the north side higher than the south to cant the antenna away from the mountainside?
9. Will the MFJ be adequate for this antenna with 100 to 150 watts?
10. Looking for any other comments or suggestions.

There is a table of resistivities at http://hyperphysics.phy-astr.gsu.edu/hbase/Tables/rstiv.html#c1. The table lists the resistivity of copper as 1.68 * 10**-8 and aluminum as 2.65 * 10**-8.

To calculate the resistance of a particular piece of wire, the formula is R = resistivity * length / cross sectional area.

So I figure then that Aluminum is 58% higher resistively,
is that correct? and a long antenna wire that might be
3 ohms, is therefore now almost 5 ohms.? That is DC resistance,
what about rf resistivity?

Topic: 2058 Message: 2071

> Galvanized electric fence wire

I've always thought electric fence wire might be a poor choice for an antenna because (most?) electric fence wire is designed to be rather resistive and lossy (since in its intended usage it supports a voltage and the current is limited). However, I've heard of so many people using it, that it must be acceptable.

> What loop formula do you use for galvanized steel wire, instead of the
> usual 1005/f formula?

This is just a guess ... but I'd say the formula doesn't depend on the wire. I'd think that the size is determined by the space around the wire (i.e., air) where the electro-magnetic fields live, not by the medium that happens to carry the electrons.

I always use the 1005/f and then trim to freq. I find the location, height, time of day and humidity all can affect the length. Formulas are for starting points. Best way if over 200 watts is to feed with 450 ohm or 600 ohm line and a good balanced line tuner, "Z" Match, and not worry about it. For lower power, the auto tuners from SGC or LDG are super. My Johnson Match box work well with my SB200 and the SGC tuner with the 100 watt drivers and the QRP rigs..

I recently read an article on making a fan dipole, 4 legs, for 75/80 meters from the fence wire. It was shorter and had increased band width. It also had increased loss, 85% vs 95%, if I remember correctly. That is a small loss for the increased band width to cover the whole band with the new phone band width.

Yeah, good point. :-)

It's only anecdotal evidence, of course, but a few people have written that their electric fence wire antennas performed as well as good copper wire.

I've also seen at least one reference (from I believe a respectable source) that says antenna wire resistance isn't very important anyway, even magnet wire makes a pretty good antenna.

Andy

I acknowledge that, but I have found some of those claims lacking
in credibility. Some of the claims were that the operator connected
to an existing fence and it worked swell. But what can one compare
that to? I did not think the operator had a copper wire fence of the
same dimensions and layout to compare with.

Of course, it is different if one makes a similar run of each - but I
thought
the fence guys were actually trying their fences...at least in some of the
cases.

#12 ga cu insulated wire is pretty good although you need to use less wire while the insulation lasts as the lengths should be less by maybe about 5%.

I've sucessfully used Aluminum electric fence wire (17 Ga) for a friend's stealth antenna that was routed underneath the eaves of a house. One must be careful with connections and use that aluminum conductor goop at the connections. Also, aluminum is very soft and will eventually break where it's flexed. We used lots of electric fence insulators (in this case painted to match the house paint for stealth). The antenna has worked for over a year now, maybe approaching 2 years. I do have some rolls of aluminum wire for setting up temporary emergency antennas in the event of a hurricane but I've no intent to use it for anything permanent as without lots of support points like every 12 feet or so, it won't last long. In normal weather conditions, I expect the aluminum to last for weeks or maybe months. Our 80m loop here is made from insulated 14ga wire and it has been up over 2 years without breakage. We keep it up with small nylon cords at the top of some old 15 ft tv antenna masts although we've had several cord breaks - necessitating a few minute of repair.

Our antenna does a super job of blanketing the whole state with nvis mode on 80 and 40m, making my vertical appear almost like a dummy load in comparison. My vertical does do 40 m dx (and presumably 80m dx) that the loop can't touch though.

best regards,

Charles

Buy it at a farm supply store, such as a Tractor Supply Store (found in most locales. It is available as #17 and #12. You can tow a car with the #12.

HI,

For what it's worth, I have used steel electric fence wire (real cheap and strong) for both antennas and buried ground systems .... The particular antenna system I used it for was to run a long beverage antenna .... hanging it in trees about 7 or 8 ft above the ground .... I used the insulated nail in holders they use for fences. It is also good for buried radials as the wire that i used comes in 2 1/2 ft rolls and comes off very easy .... I just run it along the cut in the sod ... I used a hand wheel .... the kind they use for forcing the rubber spline on window screens .... looks a little like a pizza cutter.

They only problem I found was that it was not great stuff to solder.

2084. Ladderline vs Coax

Yahoo group: SkyWires
Date: 2007-01-03 04:14:32 UTC
From: AD5VJ Bob
Topic: 2084 Message: 2084

I am thinking of doing something I probably should have done from the beginning long ago and that is to use 400ohm ladderline as
feedline to my Homebrew 80 meter double bazooka instead of double shielded 75 ohm cable TV coax.

My goal is to end up with less incoming signal loss than with coax feedline. That is what I understand is the advantage to 400 ohm
ladderline, is that it is "less lossy" to the point of being totally lossless.

So my question is this three fold:

1. If I use part 400 ohm ladderline and part 75ohm coax, at what point (percent difference in lengths) does it start to make a
considerable difference in feedline impedance?
2. Will changing out part of the coax to ladderline make *any* noticeable difference in reception or do I have to change it all to
notice a difference?
3. Is it worth the trouble at all for received low level signal strength or should I just stay with what I have?

It's a matter of what you are needing or intending to do.
If only 80 meters, keep the coax. Loss is low for 100 foot at 80 meters.
If multiband, use 450 ohm line and tuner.
If it has a long feed line, over 100 feet, use 450 ohm line.
If over 300 watts, use 450 ohm line.

Healthfully yours,
Don W4BWS

2089. Any Thoughts on using Stainless welding wire

Yahoo group: SkyWires
Date: 2007-01-03 08:48:21 UTC
From: madatweak
Topic: 2089 Message: 2089

Has anyone ever tried Stainless weldng wire akin to copperweld. I've got a roll of copperweld & I find it only lasts a 6 months before going rusty - but then I could have a cheap & nasty copperweld as Im sure there must be differing qualities. I noticed at my large hardware store rolls of stainless welding wire about the same gauge as copperweld & sold by the spool. Apart from the termination of feedline I thought it might last for a long time - Any thoughts ?

Pointing our the advantage of CopperWeld wire (copper coated steel) for antennas. With skin effect, your RF is in the copper coating, while the steel resists stretching. I haven't priced steel fence wire, so I assume that it's probably much cheaper than CopperWeld. I have used CopperWeld in a number of antennas with good results.

As long as you don't nick the copper on the CopperWeld, it shouldn't
rust. The oxidation on copper isn't rust.

Hi Bob,

Well it is not clear exactly what you intend to use the antenna for .....
eg: SW listening across HF band? Hamming .... on 80M or on more 'one
band? If so, QRP, barefoot, or QRO?

You mention using a Double Bazooka built for 80M and fed with TV coax
cable. The bazooka is a single band antenna coax fed. If you feed it with
balanced feedline it will not be a bazooka .... hi hi but simply a dipole
made partially of coax ... hi hi.

Let's try to answer your questions:

1. (does it make a difference) .... well coax and balanced line does not
easily match .... open wire line is 'balanced' and coax is 'unbalnced' ....
you need to take this into account .... especially if you are going to feed
power to the antenna. If you plan to use your dipole on a single band then
the best plan is to feed it with coax ... if you are going to use it for
multi-band operation then you will need to feed it with open wire line ...

usually coupling to your transceiver with an antenna tuner. If you are going single band .... then the impedance difference makes a difference. If you go mult-band then forget impedance and expect hi SWR and use low loss open wire feed line. If it is a receive only situation then it doesn't make a whole lot of differenced either way.

2. No

3. No, stay with what you have.

Jim, VE3CI

Yes I do have a tuner which I use for 160 when I make the double bazooka a "T" Vertical with my adapter here in the shack, but other
than that no tuning.

The Bazooka is very broad banded and covers 80 es 75 for me.

I have worked a lot of DX from it just think I might be able to do better with the ladderline. Now some others have said open wire
600 ohm line might be an improvement as well.

2099. tuner at loop feedpoint

Yahoo group: SkyWires
Date: 2007-01-03 21:55:39 UTC
From: n4lcd
Topic: 2099 Message: 2099

Has anyone ever used an unbalanced tuner, such as the Icom AH-4 or the SGC-230 or any of the other tuners like these, directly at the feed point of a loop skywire?

2100. RE: [SkyWires] tuner at loop feedpoint

From: Paul MW0CDO
Topic: 2099 Message: 2100

Yes, I do.. almost!

I have a 60m loop up and the feeder is simply a continuation of the same wire that the loop is made with.

This "feeder stub" of two wires about 2m / 6ft long is driven by a SGC-239 and works all bands 160 - 10m.

See my simple web page for further info.

2101. and for ground radials?

Yahoo group: SkyWires
Date: 2007-01-03 23:50:35 UTC
From: Jeff
Topic: 2101 Message: 2101

Since we're on the topic of wire, what kind of wire for ground radials
is recommended? I've seen online all kinds - bare or insulated,
buried or laid on the ground, and that it really makes a difference
and that it really doesn't. What to do???

Thanks and 73,

Jeff, KF5KWO

Mig welding wire will rust in the open.

The copper coating is very thin and not intended for lasting
protection from the elements.
The copper coatings main purpose on welding wire is for a low
resistance connection to the mig welding weld current.

If anyone had done a search for it they would have found that
Copperweld wire ,is not mig welding wire.
It is specially made electrical wire , steel with a hard bonded thick
copper coating primarily for the telecomuniactions industry.

http://www.copperweld.com/cwwire/cladstel.html

Mig welding wire is not the same thing.

I used multi stranded stainless wire that I got from a fishing supply
store. It was intended for deep lake trout fishing in the great lakes.
The 19 strands overall diameter was about .020".
It worked well and I never had any problems except for it singing in
the wind.

All I can say is that it must be inferior material. The only time I've had it rust is when I've nicked the copper and exposed the steel.

I agree. I've had #16/18 copperclad up for 15 years without issue. It has withstand windstorms and pretty extreme icing. And it is nearly invisible in a CCand R neighborhood!

It would appear that there is a great deal of difference between
copperclad steel antenna wire
and copper coated steel welding wire. The welding stuff appears to have
a copper wash just thick enough to give good electrical contact as the
wire is fed thru the welder. The copper coating on copperclad antenna
wire is apparently a good deal heavier. I've got a small wire welder and
I've never used any of the copper coated wire and was surprised to hear
of it. I've never used anything other than the fluxed wire in my welder
and that stuff is much too brittle
to attempt wire antenna construction.

From: AD5VJ Bob
Topic: 2113 Message: 2113

I am about to rebuild my CF dipoles and Vees.

Before I start this project, however, I would like a concerted opinion as to the best type of wire and setup to use and the least
expensive supplier to use.

They will be strapped to the side of a 40' Rohn25 Tower at about the 35' level. Run will be around 100' into the shack. I would like
to feed it with ladder line this time and would also like for it to be at min good for 200W up to legal limit.

I am considering litz wire or stranded copper, but cant make up my mind.

All opinions and ideas are welcome.

Hi,

Not sure what your arrangement will be .... eg multi dipoles/Vee's .... each resonant in a particular band and fed with a single balanced feed line .... or a single dipole or Vee to be used all-band .... fed with a single balanced feed line. In either case the feed line will be attached and dressed along the tower length and back to the shack. I suggest you take care in dressing the ladder line as it goes along the length of the tower .... I would suggest it be dressed at least 6" from the tower and held in place with insulated stand-offs. Put a gentle twist in the ladder line which will help isolate it inductively from the tower. You will have no trouble feeding the antenna with 200 watts.

As far as the antenna wire is concerned .... make it copper ... and 14 tor 12 gauge. Stranded copper works well .... it is strong and will last forever .... hi hi .... However, from the point of view of ease with which it works I would go for the more modern 'flexible' copper wire. There are different kinds ... the more economical 'flex' wire is plastic covered and

has the flexibility of standard cab tire cable. It is almost impossible to 'kink'. If you use standard stranded copper #14 or #12 it is difficult to lay it out and get it up without kinks ..... while the plastic covered flex wire is a joy to use. It is especially good in my applications as I have a tilt over tower which means loose wire antennas when the tower is down. There is a newer flexible copper antenna wire available now that is uncovered. It is virtually like rope .... you can actually tie it off like rope. Great for portable operation .... much more expensive.

You mentioned litz wire .... I am unsure if it is readily available in sufficient wire gauge/strength to be used as antenna wire. The difference between antenna wire and Litz wire is that individual strands or bundles of strands are insulated. The reasoning is that by insulating the strands the actual surface area of the wire will be increased. This is advantagous when winding physically small inductors. From the point of view of antenna applications the advantage disappears.

In summary .... a ladder feed line, antenna tuner, and single multiband dipole or Vee is an excellent antenna. However, If you are going to use a number of resonant dipoles all fed with the same feed line ... eg the SWR would be reasonable for each band .... I would go for coax. The difference in line loss between 100' of ladder line and coax when the swr is low hardly justifies the added complications of feeding with ladder line. Even if the SWR goes up to 3:1 .... if you use one of the readily available and economical ATU's your radio will be happy .... you will have quick QSY facility and the difference in the amount of RF you radiate will be negligible.

I know the best would be to run the wire through pulleys and ropes attached to trees but what about stringing insulated wire straight through the tree limbs with no ropes,pulleys etc with one corner of the loop being a mast with weighted rope and pulley to allow slack if needed? What about the insulation wearing through and direct contact between the wire and tree?

Mike,
I have mine in and around the trees, around trunks, over limbs, you get the idea. Mine worked good for about the first couple of years, I used 12 gage romex, I bought a couple of spools from a local home improvement center. I used to be able to use my tuner to adjust it so I could use it from 160 to 10 Meter. Now I can't tune it for 160, I suspect the covering has worn off of the copper wire and is just too much for my tuner to handle. I would say if it is going to be a temporary set up,go for it, BUT if you plan on it being long term, I would suggest you not do it the way I did.

Mike,
Some have a real disagreement, but that is the way I have run My large loop full wave on 80 meters, for about 5 years now, I sometimes use Green Plastic trimmer line over tree limbs for support.(Line will last a couple of years) it does come down (Breaks from time to time) Myself Never run over 100 watts SSB, 2nd I feed it with 300 twinlead and interface with MFJ-941, My loop works that way for Me. it is insulated #12 wire.
I NEVER run high power. and always set tuner for best match .
Good Luck

Mike:

I'd be afraid I would constantly be having to re-hang the wire, or that it would get all tangled up in those doggone tree limbs and I would have to cut and splice it to get it back up there.

For my 480-foot horizontal loop, I use some of the relatively cheap but remarkably strong rope sold by The Wire Man or by Radioworks. I've found lots of other uses for the stuff, too. I used 45-degree elbows for small PVC, drilled a hole in the crook of the elbow, and ran short pieces of the rope through those holes, tying them tightly. Then I used a slingshot and cheap fishing reel to shoot a fishing weight over tree limbs. Then I used the fishing line to pull up the ends of the ropes, connecting one end to the rope loops on the PVC elbows and the opposite end to a couple of nails in the tree trunks, low enough for me to reach but high enough the neighborhood kids can't reach it. The insulated copper wire of the antenna is then run through the PVC elbows, which allows some give.

I also used a couple of bungee cords between the rope and the rope loops on two corners to give it some spring in wind. It really sounds a lot more complicated than it is. The antenna has been up for six months now and came through some pretty good storms just fine.

My loop is tied off at eight trees around the backyard. It's not as high as I would like but it's the best I could do. It also runs through some tree limbs too high for me to do anything about it. I know rubbing against the limbs will eventually wear through the insulation but so far so good. The thing works wonderfully...probably the best antenna I've ever had.

Catch me on the air and I'll tell you more. Good luck with yours!

If using rope and pulleys in the trees, How would I pull the wire up without hanging on all the limbs on the way up? There is probably a easy way but I just can't picture it shy of using a bucket truck.

I have a sloping delta loop over my house now without difficulty. On rare occasion I'll run 500 watts without RF problems in the shack--and I'm on the second floor. I have a bundle of cut counterpoise wires attached to the rig and another set for the tuner. DC ground is rod just below the shack.

There are always possibilities of problems with nearby antennas where one can get zapped by induction or by other equipment having trouble or causing noise.

We helped a friend in need of a stealth 80m antenna by putting up a loop under the eaves of his house. It's about the right length but only about 7-8 ft off the ground and it runs near lots of rain gutters. At 100 Watts, it works, he gets out (NVIS mode) fairly well and doesn't have lots of noise on receive. As I understand it neither he nor his wife nor their cat have been electrocuted nor has the tv set blown up - and so far no gestapo from the neighborhood deed enforcment cabal have stopped by to threaten or complain.

In a word - success!

best regards,

Charles

Does anyone know if there's a problem putting up a loop skywire, held
up by several trees, that are around my house, so that my house ends
up inside, but below the loop? (Shack is inside my house.)

On the other hand , about 28 years ago as a novice , I built an antenna simalar to the one described in this text. Since that time , my hair has turned white , I have suffered three heart attachs and two strokes , I have lost and regained my eyesight , had two back surgeries, lost a kidney and lung to cancer , my wife left with a prune picker, my children have all left me and gone else and reproduced . The antenna seemed to work well and has grown over the years . If I had it all to do again , I would have started sooner , build the antenna . Chuck Wq5B

I don't have cable and when I transmit on 10m with 100w I overload the receiver in my TVs. The TV antenna is in the attic and at least 25ft from any point of the antenna. My loop is 300' and goes around my house and backyard. I've tried low pass filters on the radio and high pass filters on the TVs with no luck. Solution is that I don't transmit on 10m when the wife is home. I also had to get rid of the touch lamp in the basement. HF turns it off and on and it's noisy.

That's pretty much my set up here. I've got a 160 meter loop strung up and down around and about at weird angles -- up as high as 50 feet and down at maybe as low as 15 feet where it is caught in branches. I just worked Burkina Faso on 75 meters tonight. It all wraps around my house, and no RF problems on 75 or 40. When I run the Clipperton amp I have RFI problems on 20 meters. Weird things happen like the GFI plugs in our upstairs bathroom will trip! One day the smoke alarms started going off.

I find that the performance of the loop is really good on 20 meters so don't need the amp so much anyway.

It will be interesting to see how that all compares to the Butternut vertical I'm setting up.

I am about to rebuild my CF dipoles and Vees.

Before I start this project, however, I would like a concerted opinion as to the best type of wire and setup to use and the least
expensive supplier to use.

They will be strapped to the side of a 40' Rohn25 Tower at about the 35' level. Run will be around 100' into the shack. I would like
to feed it with ladder line this time and would also like for it to be at min good for 200W up to legal limit.

I am considering litz wire or stranded copper, but cant make up my mind.

All opinions and ideas are welcome.

Hi,

Not sure what your arrangement will be .... eg multi dipoles/Vee's .... each resonant in a particular band and fed with a single
balanced feed line .... or a single dipole or Vee to be used all-band .... fed with a single balanced feed line. In either case the
feed line will be attached and dressed along the tower length and back to the shack. I suggest you take care in dressing the
ladder line as it goes along the length of the tower .... I would suggest it be dressed at least 6" from the tower and held in place
with insulated stand-offs. Put a gentle twist in the ladder line which will help isolate it inductively from the tower. You will
have no trouble feeding the antenna with 200 watts.

As far as the antenna wire is concerned .... make it copper ... and 14 tor 12 gauge. Stranded copper works well .... it is strong
and will last forever .... hi hi .... However, from the point of view of ease with which it works I would go for the more modern
'flexible' copper wire. There are different kinds ... the more economical 'flex' wire is plastic covered and has the flexibility of
standard cab tire cable. It is almost impossible to 'kink'. If you use standard stranded copper #14 or #12 it is difficult to lay
it out and get it up without kinks ..... while the plastic covered flex wire is a joy to use. It is especially good in my
applications as I have a tilt over tower which means loose wire antennas when the tower is down. There is a newer flexible copper
antenna wire available now that is uncovered. It is virtually like rope .... you can actually tie it off like rope. Great for
portable operation .... much more expensive.

You mentioned litz wire .... I am unsure if it is readily available in sufficient wire gauge/strength to be used as antenna wire.
The difference between antenna wire and Litz wire is that individual strands or bundles of strands are insulated. The reasoning is
that by insulating the strands the actual surface area of the wire will be increased. This is advantagous when winding physically
small inductors. From the point of view of antenna applications the advantage disappears.

In summary .... a ladder feed line, antenna tuner, and single multiband dipole or Vee is an excellent antenna. However, If you are
going to use a number of resonant dipoles all fed with the same feed line ... eg the SWR would be reasonable for each band I
would go for coax. The difference in line loss between 100' of ladder line and coax when the swr is low hardly justifies the added
complications of feeding with ladder line. Even if the SWR goes up to 3:1 .... if you use one of the readily available and
economical ATU's your radio will be happy .... you will have quick QSY facility and the difference in the amount of RF you radiate
will be negligible.

Just don't turn the TV on. I've only turned mine on maybe 6 or 7 times in the last 8 years. It quickly reminds me why I don't turn it on. What a waste of time and brain cells. Spend that time with family and friends,reading or even amateur radio instead of sitting there starring at a propaganda box. Stay away from TV completely for 2 weeks and you will clearly see how I feel.

2132. SWR help needed on unconventional skywire

Yahoo group: SkyWires
Date: 2007-01-21 02:49:04 UTC
From: Kyle
Topic: 2132 Message: 2132

Hello guys. I am trying to do some activity on 6 meters before the weekend is out, since this is a 6 meter contest weekend. Pressed for time, I was trying to decide on a dipole, j-pole, moxon, or 1/4 wave radial. While weighing the benefits, I thought, why not use a skywire, and just scale it down? So that's what I did.

Since in HF you can use multiple wavelengths, I chose to make mine out of a 40' length of stranded wire 16 gauge wire. 40' makes the loop 2WL long for 6 meters based on 1005/f. I used nylon rope to suspend nylon spacers from wooden poles that hang the wire approximately 6' in the air (4.5' is 1/4wl). The rectangular loop is about 10' outside my house, so I just used a short piece of RG-58 to get from my rig to the loop. I transitioned from the feedline to the loop by soldering the loop to a SO-239 connector. My VSWR is 4:1 across the entire 6m band!

I thought perhaps there were feedline radiation problems, so I wrapped 4 turns about 4" in diameter to make a "balun" right at the feedpoint to the loop. Still 4:1 SWR.

Just to rule out the feedline, I took my dummyload outside and connected it, right after the 4 turn "balun", and the SWR is a flat 1:1 into the dummyload.

Any ideas on what might be messing me up? There are no metal objects anywhere near the loop at all. I'm hoping there might be an easy fix or that I made some stupid newbie mistake that can be fixed quickly/easily so I can get on the air with this loop tomorrow. Any ideas/suggestions?

Thanks,
Kyle

You might try a single wavelength - about 20' and turn it vertical, and feed it so it is horizontal polarized - make the cross pieces aout of 1/2 pvc....it will work fine

When pushed for time the diopole or inverted may have been a more
predictable project. I think that I would look hard at your make shift
balun . That design also would have probably worked well on the diopole ,
but for the loop I believe you could get alot closer match with at least a
4/1 balun and then do not expect a 1/1 match . How complete is your
junk box ? Insert a piece of 300ohm TV twinlead 1/4 wave length long
between the loop and your feed line and check the results. You may miss
this weekends contest , but it is all about fun isn't it and you will be
ready for the next one . Good Luck Kyle Chuck Wq5B

Let me reply to all three replies in one here:

> using a tuner? I think the 2WL and 6' above ground is killing you.
Hmm, I thought I read a loop of even harmonic wavelengths horizontal greater than 1/4wl above ground didn't need a tuner? Isn't that the basis for the loop skywire? No, I don't own a tuner yet. :(

> You might try a single wavelength - about 20' and turn it vertical,
> and feed it so it is horizontal polarized - make the cross pieces
> out of 1/2 pvc....it will work fine
Please forgive my ignorance, but I thought a horizontal loop was horizontally polarized and vice versa. I REALLY want to know this: How do I feed a vertical loop to make it horizontally polarized? Wouldn't that tend to be very directional? I was hoping to have an omni directional signal (this is one reason I gave up on the dipole and moxon for this weekend's project).

> Insert a piece of 300ohm TV twinlead 1/4 wave length long between
> the loop and your feed line and check the results.
I *might* have a piece of twinlead. If I do, I can try this pretty easily. Aparently, I was completely wet behind the ears about the impedance of a loop.

> but it is all about fun isn't it
No, it's just frustrating. I thought I knew *exactly* what I needed to do... LOL

Thanks guys for your quick replies! I guess this one weekend per year opportunity might be shot. I'd like to think that I could at least learn something from this mini-project before my wife makes me take it down.

Thanks,
Kyle

Hi Kyle,
I will be blunt.
#1 The loop will have a lower SWR if it is an odd multiple of
wavelengths ie 1, 3, 5, etc. Not 2 wavelengths.

#2 On the higher frequency bands a full wave loop antenna can be
oriented as a vertical diamond or vertical cube. Fed at the top or
bottom corner of a diamond this antenna has horizontal polarization. Fed
at a side corner this antenna has vertical polarization.
Let me clearly state this Fact."A vertically oriented horizontally
polarized one wavelength loop antenna with the bottom of the loop 1/2
wave length above ground is a FINE antenna".*

*

*Do NOT put the bottom of the vertically oriented loop more than 1/2
wave length above ground. *

*

*Good Luck and 73, Ace - WH2T 8-)

From: Kyle
Topic: 2132 Message: 2138

Thanks for the information to all involved. Albeit somewhat frustrating, it was a good learning experience. Even at 4:1 mismatch, the loop was absolutely outstanding at receiving on several bands. The 300 ohm twinlead 1/4 wave stub got the loop's SWR down to 1.7. I left it at 2wl all weekend before I took it down. At 1.7 I tried to work 6m, but the competition was done by then and the band had gone silent. So I called a friend (I am his Elmer believe it or not) 45 miles away, helped him build a dipole on the phone while I built one too. It was raining in Atlanta on Sunday, so my dipole was in my house and his was outside at about 8'. At about 70W from him, I could hear him with the 2wl loop, but not my dipole. At 100W from me, he could hear my dipole, but not my loop. :)

Based on advice from the forum, next time I'll try it higher up, with an odd harmonic. Will I need a matching stub then, and if so, how do I figure out it's length for myself? Is there a calculation for a matching stub, or was that suggestion based on experience?

Thanks for the info on the vertical loops. Are they directional? I know a cubical quad is, so I'm assuming a vertical loop is directional with a 0dB front/back ratio, much like a dipole.

2139. Again... Can a tuner be used at feedpoint?

Yahoo group: SkyWires
Date: 2007-01-23 11:49:13 UTC
From: kenwood_480sat
Topic: 2139 Message: 2139

Hello...

I noticed a post a ways back, that nobody bothered to answer. It is something that I have been wondering about myself, so I'll ask it again.

Can an automatic antenna tuner (such as the Array Solutions AS-200 tuner) be used at the feedpoint of a loop? I want to run a 50 ohm coax from the shack, approximately 50 feet (give or take a few feet) to the feedpoint of an 80 meter loop so that I can run the loop on more than one band, which is why I want to use a tuner at the FEEDPOINT instead of at the radio end. I want to avoid using twinlead if at all possible, for several reasons.

Will the tuner being at the FEEDPOINT (instead of at the radio) remove any possibiity of heat being generated along the coax, when tuned to bands other than the fundamental resonant frequency of the loop (80 meters)? As far as I know, it should, but at the same time, I also realize that there will be a loss of power between the coax and the antenna, via the tuner box.

If this would work, just how much power should I expect to lose because of the mismatch at 40, 20, and 10 meters, through the tuner? Basically, I guess I'm just trying to determine if I could still expect to have a decent usable amount of power on the bands other than 80 meters.

Any help with this is appreciated. Thanks...

Hi,

Some tuners are designed to be located at the antenna. I think these all come in outdoor rated enclosures. I do not know about the specific model you're referring to. Also, I don't know the tuning range over which any will operate. It might be necesssary to create a balun to bring the impedances into the range the tuner will work.

There is always frequency dependent loss in coax which will become heat, even if tuning is perfect. There will be some power loss in the tuner. However, things will work much better than no tuner and a tuner at the antenna should work a bit better than one in the shack. Compared to the complexity of an antenna that adjusts to the particular wavelength, there is probably not enough significant improvement to justify the added complexity over what is achievable with just the tuner.

Hopefully others can ellaborate more on your questions.

Excellent question and one that also interests me.

I am seriously considering a horizontal loop and
would like to put my SGC-230
http://www.sgcworld.com/230ProductPage.html
at the feed point of the loop.

This is an unbalanced tuner and is functionally
the same as the Icom AH-4 and many others.

Here's a ham using an AH-4 and he prefers
balanced horizontal loops to unbalanced
long wire antennas with the AH-4.
http://home.comcast.net/~hamlakemn/ah4/ah4.htm

An interesting comment on loops with the AH-4:
http://home.comcast.net/~hamlakemn/ah4/ah-4faq.htm
Q:
How do I connect the AH-4 with its single-ended output to a balanced antenna?
A:
You can use a balun, but make sure you use a type that can work with
a wide range of impedances. Some current mode baluns are really only
designed to work at a specified impedance, such as 50 ohms. Also note
that not all baluns work at 160 or 6 meters. You may be better off
building your own. You will note that my flat top does not use a
balun. I've been told that this won't work. My log book says
otherwise and I enjoy full coverage of the 160-6 meter bands with one
antenna! At some point in the future, I hope to provide construction
information for a balun that will work well with the AH-4 and
balanced antennas with a wide impedance range.

Does anyone have any experience doing this?

73,

Paul

I don't know anything about that particular ATU. I'd certainly contact the manufacturer and find out the range of impedance and voltage for which is it rated.

The upper and lower limits of both impedance and voltage will be needed to be known for any transmatch you use, and you should likewise get a theoretical pair of ranges for the loop itself.

Once you know what the max/min impedance (Z)/voltage (E) is for your loop, find transmatches that can operate beyond that range. If you cannont then you will either need not operate outside those ranges, or otherwise alter the Z and E to be within the transmatches range. Otherwise it may become damaged.

Other than the Z and E considerations, weatherproofing and mechanically supporting the transmatch at the loop feedpoint, and supporting the transmission line, are the remaining issues with placing the transmatch at the antenna feedpoint. This is true of any antenna, loop or otherwise.

> Will the tuner being at the FEEDPOINT (instead of at the radio)

> I also realize that there will be a loss of power between the coax
> and the antenna, via the tuner box.

Well, it depends upon the swr between the transmatch and the transceiver. Even with the best match there is some coax loss but provided you are usng a coax rated for the power you are transmitting at you should be fine so long as the swr on the coax is low; swr of 1.5 to one; maybe as much as 2:1.

You still need to be aware of the swr on the coax.

Just because the transmatch is at the feedpoint doesn't mean the swr is always 1:1 rather it depends upon the setting of the transmatch and how successful the impedance match was for each frequency.

The "Antenna Book" and other sources show losses when using a specific coax loss and at a given swr loss. You just cross the lines and you see the actual swr loss in the transmission line. In fact in the past few months there was a good QST article on the subject.

Using one of these tables and inserting your coax and expected (or measured once it is all up and running) you will be able to determine the actual loss in the coax, and from that calculate the power lost/heat generated.

> If this would work, just how much power should I expect to lose
> because of the mismatch at 40, 20, and 10 meters, through the tuner?

If the transmatch ("tuner") is well build losses will be quite low. Even using MFJ transmatches, which are not known to have the best materials, I measured some losses a few years ago and they were in agreement with other figures I've read others discovered. Usually less than 1 dB of loss. Much of the time quite lower. I have never measured a 2 dB loss through any of my transmatches, but to be fair I don't normally meansure their loss.

I'm sure there are programs out there to estimate such losses. It seems to me the newer "Antenna Book" volumes has a CD-ROM with such a program (I could be wrong about that - it is a dim memory, but I -think- is is correct).

> Basically, I guess I'm just trying to determine if I could still
> expect to have a decent usable amount of power on the bands other
> than 80 meters.

I would expect the answer to be yes. The further the Z and E range (both min/max) the more trouble you'l find, so there may be a number of frequency ranges for which you have some difficulty matching.

If so, investigate methods of altering the Z and E.

Altering transmission line length may be a problem in this case. The antenna is at the feed point and to do so you'd have to have loops of transmission line up there (coax I'd assume due to interactive issues) and a means of remotely switching each in/out of the circuit.

A balun of some type is a possibility. Select carefully. Too much power may cause damage. Also as you range farther from the designed frequency of the balun many become less and less efficient. It can be tricky designing a balun for very wide frequency ranges, and an all-band balun is certainly that. But it can be done. Here is one of the best discussions I've seen on the subject, but read the entire PDF:

http://audiosystemsgroup.com/RFI-Ham.pdf

Another consideration is your operating convenience. When you have troubles with your transmach (you will, it is a mechanical device after all) you will have to go up to the loop feed point to investigate (or bring the feed pooint to you). This, along with weatherproofing, are the main reasons most people I know use a transmatch at their operating position (of those that do so).

Neither location for a transmatch is right or wrong. It is a combination of the variables for your operating location and your preferences.

So the short answer is "yes" but there are caveat, as always.

> balanced antennas with a wide impedance range.

When I used a SGC-237 (which I gave up due to poor construction and poor tech support) it had a SO-239 as the output connector. The supporting plate upon which the entire thing was built served as the ground plane for the device, and therefore also as the shield/ground side of the feed point. With that unit you had a number of predrilled holes along the perimeter of the plate. And or all of these could be used for the 'other side' of the feed point.

When used on a loop you just connected one end to the SO-239 and the other to the plate. Alternately you could modify soimething to connect to the SO-239 and break-out that connection to two appropriate wire connections.

If you use a SGC every instruction booklet I've seen recommends placing a bucket over their weatherproof box. Then again, I just read one of their instruction manuals at the local OEM and it repeatedly stated a transmatch "must" be located at the antenna feed point. This is wrong. It is so obviously wrong most hams with less than one years experiece know it is wrong. I find it difficult to trust companies after they hold to such obviously wrong beliefs. Caveat emptor say I.

In any event, jerry-rigging a connection point for a loop antenna to an auto-tuner like the AH-4 or various SGC coupers ought not be very difficult. If nothing else mount a PL-259 in one end of a short piece of PVC (with a cap on each end, sealed, and painted black) and provide wing-nuts or nuts and bolts as terminals for your antenna wire on the other end.

Use a little wire as is reasonable, make sure they don't get shorted together, solder the connections, and make them mechanically strong (solder won't do that, it only provides electrical conduction, not physical strength). Any 'break out box' that does all that will be fine.

If you find you need a balun it too could be enclosed in your break out box. Or not. It is your choice.

> Can an automatic antenna tuner (such as the Array Solutions AS-200 tuner)
> be used at the feedpoint of a loop?

Someone will correct me if I'm wrong ... but I think the two main characteristics of tuners meant to go outside at the feedpoint, are (a) weatherproofing, and (b) automatic with no human intervention required. You could take most any autotuner and put it in an appropriate box, if you want to save some $ and have the time.

Otherwise, there's no inherent electrical difference ... though some models might be better suited for tuning particular impedance ranges than others.

Antenna matching/'tuning' devices are always best put at the antenna; but for convenience sake many of them go indoors.

Hi

I´ll give a short run of my setup.
Had the problem of bringing my 450Ohms feedline into the house and when I did I just couldn´`d get
rid of the RFI.
So I made an L-match in a plastic box (waterproof and located remote about 30 feet from the shack). From there coax to the shack.
Then a control box inside the shack with a microchip (picaxe) and a picaxe in the L-match. Between I use a RS232 line to talk to
each other.The control box have a switch giving command for each band to the L-match to go to predetermined taps on the inductor and
set the capacitor to the required capacitance.
The system is more like a remote antenna tuner for open-wire feedline.I have tried it up to 500W with no problems.
I am refining the system to RS-485 to avoid any disturbence on the system when transmitting. Also adding LCD display
in the control box to be able to read certain parameters.Maybe autotuning in the future.
The loop is a 80M loop up abt 50 feet feedline 450 Ohm open abt 20M long to the L-match/box works on all bands , best on the higher bands

I guess You could make it more simple by just having relay's switching for each band if You want to avoid microchip's

> might be better suited for tuning particular impedance ranges than others.

I would generally agree with this point of view. I would add that you must also account for user control. Not all auto-tuners are 100% automatic, and some have optional settings, for example to lock a tuned setting. This can be a very nice feature, otherwise you sometimes find yourself in situations where a minor flutuation causes a re-tune to take place, which you from an operational stand point know isn't required.

Other times just the opposite takes place, and while you may have a tuning solution you wish to force a new tuning solution to be attempted.

Just remember the control wires for such things.

> Antenna matching/'tuning' devices are always best put at the antenna; but
> for convenience sake many of them go indoors.

Here the path begins to get rocky. I try not to make 100% statemtents as there are far too many exceptions.

I will certainly agree the strongest reason to bring the transmatch indoors at the transceiver is convenience. I will not agree the transmatch is always best placed at the antenna [feed point].

1) The two statements already are in opposition; They can't both be true.

2) You are assuming the antenna [feed point] is the best place for the tuner, I _assume_ due to transmission line loss considerations. There are many cases where such loses along the transmission line are so tiny as to not be significant. The ham on the other end of the skywave will never hear the difference and in many case we amateurs don't even have equipment accurate/precise enough to measure the loss.

Now I am biased. Lets get that out in the open.

I _like_ the transmatch sitting right on / beside my XCVR. If I am experiencing less than a 1- or 2-dB loss that is far too little power loss for me to go through the additional pain of having a transmatch out of sight. If you are going to place it far out of reach where it

requires ladders, good weather, and such concerns to fix it, or just remove the malfunctioning transmatch, I am not interested. Not even 0.00001% interested.

For me, a loss so small no one can hear, and many can't measure, does not come even close to making up for such concerns resulting from removing the transmatch from my operating position.

But others want that last 0.1-dB if they can get it and they don't care if that puts their transmatch 50-feet up a tower they can't themselves climb. Both points of view are OK and both are correct from their point of view.

As I say, beware 100% unchanging statements. There are usually multiple 'right' points of view.

Hello again... Original poster here...

It seems I made a mistake regarding the actual unit that I was wondering about, the Array Solutions AS-200 tuner. It is not a tuner itself, but a 4:1 balun that is merely made to be used in unison with a tuner. It has an SO-239 for coaxial input from the radio end, and then two stubs for feeding the dipole, loop, vertical, whatever.

Can someone take a look at this unit, and tell me if it could be used in my specific situation?

I have a Kenwood TS-480SAT, which has the built in auto-tuner. Can I run about 50 feet (give or take) of 50 ohm coax from the output of my radio, to the Array Solutions AS-200T (which has an SO-239), and then attach the ends of the 80 meter loop to the two stubs on the AS-200T?

Would it be possible to use the 80 meter loop on multible bands using this baun and my radio's tuner?

Please take a look at the AS-200T and tell me what you think, before answering. It can be found at:

arraysolutions.com/products/baluns.htm

Here's the deal...

I am trying to put up an 80 meter loop that I can use on more than one band, BUT using my radio's existing built-in antenna tuner. Obviously, this presents a problem if I wanted to use twinlead AT the radio, since the tuner is not EXTERNAL, but INTERNAL.

So, would it be possible to take run a 50 foot (give or take) coax from the output of my radio, all the way to the feedpoint of the antenna, using one of these AS-200-tuner baluns AT the feedpoint of the loop?

Please follow the link I posted and take a look at the AS-200 line. The AS-200(T) says that it's designed to be used with dipoles, zepps, and verticals. Since it mentins dipoles, I figured why no a loop? Take a look at the construction and get back to me with your opinion.

arraysolutions.com/products/baluns.htm

>ends of the 80 meter loop to the two stubs on the AS-200T?

Yes. Should likely be fine. So long as you are using low power to tune-up (does that Kenwood automatically drop power when you use the internal tuner?) I'd expect the worse case scenario is it just doesn't find a tuning solution. Hook it up and try it out. Keep a little cheap sheet as to mode and frequency.

>Would it be possible to use the 80 meter loop on multible bands using this
>baun and my radio's tuner?
>
>Please take a look at the AS-200T and tell me what you think, before
>answering. It can be found at:
>
>arraysolutions.com/products/baluns.htm

That balun is expecting a 200-Ohm load on the antenna side and reducing that to 50-Ohms on the XCVR side of the balun. In many places the loop will be quite far from that ideal 200-Ohms. On the other hand, depending upon the range of the internal tuner in the Kenwood, you should be able to match outside that ideal range. You will know how far after you try it.

Whatever the antenna's impedance is will be reduce by 1/4 going through the balun. As you get farther from that ideal impedance the balun will do this with less efficiency.

The answer is yes. The strategy of placing an ATU at the feed point of an antenna is a fundamental one at SGC. You can check out their site for all kinds of information along these lines. Personally I have not used this approach since I have never owned an ATU. However I have fed different kinds of loops on multiple bands using an antenna tuner at the shack and feeding with open wire line. I can appreciate the convenience of feeding the antenna with coax.

The best loop I ever used was a 70' foot loop (20M) which I fed a number of different ways; coax, 70 ohm balanced line, and 300 ohm balanced line (with a tuner). This loop was vertically oriented (using bamboo spreaders) and mounted 30-40 ft in the air. It was a dynamite antenna on 20M ..... and worked equally well when fed the different ways as mentioned. However, I did notice that it also worked surprisingly well on other frequencies when fed with 300 ohm balanced line with antenna tuner. It worked on 40M as well as higher frequencies.

I notice that SGC markets what they call a 'Stealth Antenna' which is an 80' loop (just a bit longer than a 20M resonant loop) and feed it with an

ATU mounted at the loop. I think 80' is significant .... in that it is not resonant at any Amateur frequency. They claim it will work effectively 80-10M .... depending how high you can put it. Given my experience with a 70' loop I believe the claim. I know for certain that such an antenna will run rings around portable 'screwdriver type verticals' on all bands.

its doable.... I was just reading about nmaking a
ground antenna made up from coiled rg-59.. A big flat
coil buried in the ground.

For what your thinking Id think you would have to
sever the shield somewhere to allow for an air gap
into the core.

Mike,

It seems to be a helluva way to waste all of that coax, but, it's yours to do whatever... Just use the shield and leave the center conductor alone...

The effect will be the same as solid copper of the same diameter as the coax shield (not the jacket)... I use # 12 COPPERWELD for the iron core strength... A 160 meter loop is more than 500 feet long... That's a lot of RG58...<big grin>

2161. Re: [SkyWires] Using coax for loop wire

Yahoo group: SkyWires
Date: 2007-01-25 17:31:06 UTC
From: Andy
Topic: 2152 Message: 2161

There are different ways to use coax to make a loop.

(1) You could treat it as one fat wire (just the shield) and make it into a loop. The center conductor could be shorted to the shield too but it's not doing much used this way. I guess the advantage of coax is that it is like a very fat wire.

(2) You can make a "shielded loop" by connecting your balanced feed to only the center conductors on both ends of the loop, and then ground the shield, but you need to NOT make the shield into a complete loop but keep it open at one place, so that it doesn't make a faraday shield. These shielded loops are often used as small receiving antennas, with good directionality and noise rejection capability. Some say the principle is to shield the electric field and respond only to the magnetic field, but I've also read that isn't really how they work.

The above are two very different ways of doing it and I expect they behave quite differently.

Andy

You can also make your loop by first making a Bazooka antenna and adding a half wave of wire to complete the loop. This gives a broader bandwidth and the loops lower noise.

I already have a home made 80 Meter Double Bazooka in an inverted V configuration and it works quiet well as it is with 200W. Thirty
feet at the apex, 20 feet at each end.

Where do you feed the bazooka once you make the half wave to complete the loop.

It is being fed at the center of the apex right now.

The only switch I could find is the MFJ-1706 at $100 OUCH! Would a DPDT knife switch work? Would two DPST swithches spaced 4" apart(Same spacing as my feedline) be better?

2170. 2-turn loop

Yahoo group: SkyWires
Date: 2007-01-27 02:40:13 UTC
From: icra@galaxynet.com
Topic: 2170 Message: 2170

Recall questions being asked about a 2-turn loop...

Can not recall if it was on this list or another, but know it did not get a good answer because
I had the same questions.......

Well, here is the answer......

In the Feb issue of World Radio is an article by Thomas Kocourek, N4FWD on the Zipcord Loop.

He came up with the empirical formula 887/frequency in Mhz=length in feet.

He does suggest cutting it a little longer for cut and try final tuning.

Mark the 'A' wire and the 'B' wire...put it up as you would a normal loop and connect one end
of wire A to the opposite end of wire B to form a 2-turn loop.

Put it up as a vertical loop or horizontal loop.

He does state it can be used asa multi-band antenna with a tuner and gives a table of data on freq, SWR, R, and X.

He does not give comparisions to other antennas, but does seem to suggest it would give a 3db gain over a single turn loop....

> knife switch work? Would two DPST swithches spaced 4" apart(Same
> spacing as my feedline) be better?

This is a question I've asked off and on of various people for years.
The basic reply I get is two-fold....

On the one hand any 'breakout boxes' or 'switches' we are going to use
on HF are so small when compared to a full wavelength that the tiny
fraction of discontinueity our homebrew item constitues will not
result in an appreciable impedance bump.

One way to test this should be just as with a balun. Send a low power
RF signal through it (into a dummy load) and measure the swr and/or
impedance coming out of the unknown device. Obviously, if the
transmitted signal is ~50-ohms, as is the dummy load, and the swr
remains very close to 1:1, then the device under test is not creating
any significant impedance bump (test at a range of frequencies for
which you plan to use the device).

The second point is RFI may occur. This is more likely in an
unbalanced situation. It may be the metal shielding around the
enclosure needs to provide better RF isolation. (Or to be present at
all, if the breakout/switch was built in plastic or open-air.)

In the first case, that of the balanced transmission line, the
currents are equal-and-opposite so naturally they don't radiate much
at all.

In the second case, and only if RFI is a problem, do you need to take
a close look at shielding (unbalanced situations).

None of which answers your question directly! Hehehe....

I personally think you'll be fine.

If you have a small flourescent bulb around you could test it. I've
heard (but not tried) using the small replacement bulbs for the 12-v
rechargeable Coleman latern-look-a-likes. Run the bulb along the
length of the balanced line and see if there is a significant change
at your knife switches.

Some others may be able to expand on this, as I've only read about it
and never actually done it myself.

Let us know what you find out!

That looks exactly like what we were using in 1952 when we were feeding
a dipole with tv leadin and switching between the homebrew qrp xmtr and
the Hallicrafters S38. Not much more money either. I would think that
would work nicely for switching between antennas.

Well, that explains why we could use it back then. The homebrew was only about 5 w. I did notice that they're still selling the same brand that we used back then.

Is there such a beast that allows switching from one antenna fed with 600 ohm ladder line to another antenna also fed with 600 ohm ladder line? I would like to be able to switch between the loop and a 160M dipole without having to un-attach / attach feed line from the tuner.

2179. Re: [SkyWires] Using coax for loop wire

Yahoo group: SkyWires

From: Donald Sanders
Topic: 2152 Message: 2179

You feed the antenna just the same as you would with out completing the loop. You may have to adjust the feedline length to see 50 ohms if you don't use a tuner. Personally I like my 80 meter loop best with the 450 ohm ladder line fees and the Johnson matchbox for all band operation. At 60 feet it does great. I am planning to make the vertical antenna in the new QST and feed it with my SGC auto tuner. It should operate 160 thru 15 meters. I have a vertical for 12 and 10.

Subject: RE: [SkyWires] Using coax for loop wire

I already have a home made 80 Meter Double Bazooka in an inverted V configuration and it works quiet well as it is with 200W. Thirty feet at the apex, 20 feet at each end.

Where do you feed the bazooka once you make the half wave to complete the loop.

It is being fed at the center of the apex right now.

Really?? Now that's interesting!

You can also make your loop by first making a Bazooka antenna and adding a half wave of wire to complete the loop. This gives a broader bandwidth and the loops lower noise.

>spacing as my feedline) be better?

The standard knife switch available as 'Philmore' .... also sold by RadioShack .... will easily handle 200 watts and perhaps more. If you are running QRO .... eg a KW .... I would look for something more robust.

Another trick ..... which I have used is to use KW Ezee match which is a balanced antenna tuner (link coupling) with two active connectors .... one connector for antennas in the 80-40M range and the other in the 20-10 M range ....

> Only good for 15 Watts RMS (AVG).

Actually, not even that much!

Assuming that the antenna and ladder line impedance really is 600 ohms
(that the SWR is low):

0.3 amps allows up to 54 Watts. BUT ...

50 VAC allows only 4.17 Watts.

Run 5 watts into a 600 ohm transmission line, and the voltage exceeds the 50
V rms voltage rating of the switch. At 15 watts, it's up to 95 V rms.

Make the impedance less than 600 ohms and you can approach as much as
15 Watts with this switch (when Z = 167 ohms). The impedance that matters
is the actual impedance where the switch is, not the antenna impedance alone
nor the ladder line design (or surge or characteristic) impedance.

Now on the other hand, it might not be so horrible to exceed the switch
manufacturer's ratings. The ratings might be based on throwing the switch
while voltage is present and current is flowing, which you won't be doing
(right??). Anyway, if it smokes, you're only out $4.

I'll bet the older knife switches were ceramic and could handle a lot more
than 50 V without chance of damage.

Another option, not as clean and elegant, is to use banana plugs.

Andy

Hmmmm, good point. Especially if you consider it's OK for 1500w to run through the little 16ga wire and the wire is much smaller than the material in the switch.73 , Mike

2186. How to get a line over the top of tall trees to secure antenna

Yahoo group: SkyWires
Date: 2007-01-30 15:53:29 UTC
From: k5fsp
Topic: 2186 Message: 2186

I an new to this group, and this is my first posting... I just installed my first loop antenna, and I'm really pleased with the results so far.

I've been faced with the problem of how to use the 60'- 70' tall pine trees around my home to secure an antenna. I'm 63 years young, and my tree climbing days are over. Someone may have posted such a solution as the following, but I've never seen it.

I was reading in some publication about how to construct a spud/potato gun or cannon. I decided I may be able to use such a device to get a nylon string over the pine trees. In the past, I've used the sling shot/spinning reel device, and various other methods with very limited success. I built the spud gun using a piece of 2" and 4" schedule 40 pvc pipe. You can find a ton to plans by choosing your favorite search engine and searching for spud or potato gun.

I built the cannon, and cut a short length of 2" pvc to use as a jig to pre-cut the potato to size. I then cut a square piece of cheese cloth, placed the pre-cut potato on the cloth and folded the four corners up and tied the nylon string to it. Make sure you secure the other end on the line to the bucket, as I learned the hard way when the first shot took all of my line. I had already spooled off the proper length into a bucket in a figure 8 so it would not tangle. I put the potato wrapped in the cheese cloth into the barrel of the spud gun and pushed it to the proper depth with a dowel ramrod. I charged the spud gun with Brute aerosol deodorant. I stood at a 45 degree angle to the top of the tree and fired the cannon. It completely cleared the top of the 70" tree, and came down on the other side. I was able to pull up the 1/4" nylon rope without a problem.

The total investment was about $40.00. I will share my construction details if someone is interested.

73,
Phil, K5FSP

Sorry , I never used a spud gun, at the time I needed to I had a 55# bow.. it worked great.

Id have to be careful around my neighborhood, I can see my backdoor neighbor's eyelashes while she is at her sink. ID have the cops in my backyard in a second! lol... And Id probably shoot it over her house and land a block away with all my luck!!!

For me it was easy, the limbs on my beech trees are very open and broad. Get a line over and add an old window weight. Works great.

I actually at one point was constructing a water bottle rocket assembly, I found on similar sites. They seems safer. But aiming is a bit harder!

Topic: 1615 Message: 2191

not trying to beat B&W out of their dollars, just trying to do it for less.....

I have a BWD90 which we all know, handles 1kw plus but the SWR is greater than 2:1 in certain places. calling B&W, I was told that if the antenna has any age on it at all, odds are that the BAlun is soaked (wet) and needs to be removed from the wire set along with the resistor coil and put in a stove for a few hours under low heat until it dries out.

again, I know that we are not violating patent since this sucker has been on the market well in excess of 20yrs -- does anyone know what the values of these two items - the balun and the resistor coil -- are and where I could get less expensive replacements?

also, I bought one of the wannabee B&W 82 foot grey insulated wire closed loop antennas off ebay but which is only good for ~200W. Apparently, in a moment of total dumb ass, I popped about 500W thru it and now it likes about 3:1 to 8:1 SWR. Could I take the coil and resistor off my BWD90 and put them on this lighter, more flexible antenna and thus, raise the PEP input to this shorter antenna ???

IF it would work, I think that I would have the best of both worlds by taking the balun and coil off my B&W and putting them on the 82' wannabee.

thanks

From: Donald Sanders
Topic: 1615 Message: 2193

Chas, If i remember correctly, the B&W is a version of the T2FD antenna and the feed impedance can be 300 to 450 ohms depending on the load resistance opposite the feed. I have a home brew model that has 390 ohms 100 watt resistor load and 300 ohm feed. I have a balun to feed the 50 ohm coax to the 300 ohm feed impedance. I also have used 300 ohm TV leadin to feed the antenna from the Johnson matchbox.
I believe that with a 600 ohm load you will have about 450 ohm feed impedance. So you can make your own balun and load or use their load and make your own balun.
Healthfully yours,
Don W4BWS

Apparently, in a moment of total dumb ass, I popped about 500W thru it and now it likes about 3:1 to 8:1 SWR. Could I take the coil and resistor off my BWD90 and put them on this lighter, more flexible antenna and thus, raise the PEP input to this shorter antenna ???

IF it would work, I think that I would have the best of both worlds by taking the balun and coil off my B&W and putting them on the 82' wannabee.

thanks

I have a home brew model that has 390 ohms 100 watt resistor load and 300 ohm feed. I have a balun to feed the 50 ohm coax to the 300 ohm feed impedance. I also have used 300 ohm TV leadin to feed the antenna from the Johnson matchbox.
>I believe that with a 600 ohm load you will have about 450 ohm feed impedance. So you can make your own balun and load or use their load and make your own balun.
>Healthfully yours,
> Don W4BWS

thanks Don, will go see what I can find.. I want to run this off an unbalanced load so, I should think that I am obviously looking for a 50ohm impedance. just not sure what resistor/balun will give me that with the LRM and the wire of the dipole. do not really want to have to tune this unless I am going to 6m or whatever. also, would like to see it down close to 1.5:1 or less at 75m and nearly that at 40m. certainly under 2:1 at any point on the bands. guess I need an antenna analyzer more immediately than I thought.

cheers

Dear list memebers.... I have for sale one Soft Cover copy of W2DU, Walter Maxwell's book "Reflections II- Transmission Lines and Antennas". It is in VERY good shape. No off odors, or ripped pages. One small tear at top of spine on back cover. If you only ever read one book on the subject, I suggest this one.
I will ship, boxed, and insured for $80 to lower 48 only. (About 1/2 the going rate on Bookfinder.com). PAYPAL is preferred, but I will accept USPS Money Order.

Thanks!

Greg Schippers, KC8HXO

2212. Pole Question

Yahoo group: SkyWires
Date: 2007-03-01 13:06:33 UTC
From: Kyle
Topic: 2212 Message: 2212

Good morning group. My wife and I upgraded to General over the weekend. Now we want to put up our 80m or 160m skywire. I have several questions. Here is the first.

If I need to put up a pole for my home installation, or if I try to use a skywire during field day, can I suspend the loop from grounded aluminum poles?

To do this, I was planning on using thin poly rope to hang plastic insulators from the pole(s), and then run the wire through the other hole in the plastic insulator. But my concern is that the grounded, vertical, conductive pole in close proximity would detune the loop. What do you guys think?

73,
Kyle

Kyle, those more experienced than I will give you a definitive answer. If you keep the loop a couple feet from the pole, I would bet it shouldn't present too much of a problem. At least I would try it. Loops are probably less troubled by nearby objects than most other types of antennas. (Low Q and all that from what I remember reading.)

Congrats to both you and your wife! Welcome aboard!

2216. Metal Roof Question

Yahoo group: SkyWires
Date: 2007-03-02 13:34:41 UTC
From: Kyle
Topic: 2216 Message: 2216

Thanks to Gary, W7TEA for giving me some guidance on yesterday's metal pole question. My second question is about metal roofing. One GREAT place to suspend my loop from is the peak of the barn in my horse pasture. The roof is a 12&12 pitch (very steep) and at the point is is just the right height for attaching the loop. If I attach a non conductive "stick" at the peak and use that to support the wire in that position of the loop, will the steeply pitched metal roofing underneath the loop significantly affect the antenna? I do not think the roof is grounded. Is this another, "I'd try it" situation, or should I just stay away from the barn roof altogether?

Thanks,
Kyle

Hi,

All antennas work better over good ground conditions. A large metal roof (such as a barn) serves very well as a ground plane .... I have seen several installations of vertical antennas mounted over such metal roofs and they work very well. I am not talking about making any direct electrical connection to the roof. Dipoles also seem to be enhanced. A low horizontal loop may or may not be enhanced ... i do not know.

If you put a vertical over the roof you will have a dynamite antenna.

Hi Kyle.

Let me send you to a reference to get you started:

http://focus-webapps.ti.com/general/docs/sitesearch/searchsite.tsp?selectedTopic=1653260327&numRecords=25&searchTerm=swra046a&statusCode=null

This is a paper on the Texas Instruments web site
called "ISM-Band and Short Range Device Antennas".

On page 3, the concept of near reactive fields and far
field regions is briefly discussed, the impact of
proximity of objects to antenna feedpoint impedance,
etc.

I would not call this leisure reading, however. It
may leave you with more questions than answers.

But, it is a fine review of fundamental concepts,
definitions, etc, and several antenna types (dipoles,
small loops, etc) are discussed.

In the end you may have to be willing to experiment,
take some measurements, etc.

From: Andy
Topic: 2216 Message: 2219

If I understand correctly, the metal roof would not be under the loop, it would be next to it. So you wouldn't get the benefits Jim Dunstan talks about.

I'd guess the roof is likely to offset the loop's pattern, making it somewhat more directional than it might otherwise be, but not significantly so (perhaps unless the roof is comparable to the size of the loop). It should work just the same. It can't hurt to try it!

Whether or not the roof is grounded makes little difference.

Regards,
Andy

I wish I could read the article. Was this experimentally determined or
just simulated? I ran a simulation of this through MMANA and it didn't
appear to add any gain.

2222. Rhombic vs Traingular

Yahoo group: SkyWires
Date: 2007-03-05 14:36:17 UTC
From: Kyle
Topic: 2216 Message: 2222

Thanks for the replies on the metal roof question. We laid the 160m (529') loop out on the ground Sunday. As it turns out, the loop isn't big enough to get to the trees I wanted to use as support structures. I'm crossing my horse pasture and I have to work with the structure locations given. We tried several other different patterns. Two patterns work very well with the trees we have. The first is a rhombic, diamond shape. It is *very* elongated away from square; I'm estimating the acute angles were around 30 degrees. It would be located on the downward sloping hill, over ground the entire way.

The other option is a nearly equilateral triangle. The triangle would cross a gully, then turn back across my pond that's about 1/4 acre. The ground under this one would go up and down over its path, and about 100' of it would be over water.

Both loops would be 30-50' up in the air. Dr. Ace's web page states that a circle is about 1dB over a square and a square is about 1dB over a triangle. That makes me think the rhombus might work better with respect to gain. But I want as omni directional pattern as possible, so I am thinking the triangle might be a better choice, even though I might give up some gain.

What are the thoughts & experiences of the group on this? Keep in mind, I want as omni directional of a pattern from the loop as possible.

Many thanks,
Kyle
W4KDA

P.S. the barn roof was part of the original path that I underestimated the distance on, so that isn't going to come into effect on these two design considerations. We will have to save the practical study of the "barn roof effect" for another day. :)

Hi Kyle,

I would go with the nearly equilateral triangle. The larger the area or aperture inside the loop the better. It should be more nearly unidirectional than the *very* elongated rhombic, diamond shape.

2229. Skywire/No Joy

Yahoo group: SkyWires
Date: 2007-03-12 11:52:29 UTC
From: Kyle
Topic: 2229 Message: 2229

Good morning wire antenna enthusiasts. I thought I'd give you a short note on the skywire project. Several of us met yesterday at my house at noon. My dad was a bow fisher in Florida for many decades, so I got him to come over and shoot an arrow with a string into the trees (with mind blowing precision!). In each case, we used the arrow's string to pull the rope up into place. That got our ropes up about 45'-50' from the base of each tree, exactly where I wanted them. I thought the ropes would be the hard part, but no such luck. Putting up the ropes probably took around an hour or so.

We spent the next 4-5 hours trying to get the wire up where we wanted it. The pond really wasn't a problem (used my hand-made boat to get the wire across), but limbs were. I never imagined it would be so hard to get a wire into a tree! We had 4 adults trying to coax the wires while pulling the insulators up. The wires kept getting tangled around lower limbs and branches. It's amazing how a wire can get stuck and held fast by a tiny twig 1/3 the diameter of a pencil! Equally amazing is how a wire can wrap itself around a limb nearly 360 degrees when being pulled in a direction almost parallel to the limb.

There was one tree that looked like it would not be in the way, but it was - so I fell that ~60' tree. The XYL, KI4HPP, said she didn't care if I dropped the tree, and I didn't care, so KI4SRB advised that in those cases the wire decides. Is this a wire antenna rule?

All said and done, the wire is hanging from insulators way up in trees, but the wire is slack and is still on the ground (and on the bottom of the pond). I already used my chainsaw from an extension ladder to drop several limbs. Now I have to borrow a telescoping saw to get even higher above the ladder to trim some other limbs. Then we should be able to finish pulling the wire into the air. I need to finish it quickly because the trees are all about to leaf out at our QTH.

Overall, it was fun, it was a lot of work, and it was frustrating not to finish it in one day.

I cut all the trees down that were along the path of where my loop runs. That was the only practical way for one person to put it up in one day. There's enough trees in the woods around my house that no one would ever know it.

The other option is to shoot rope through the trees, tie an insulator to one end, thread the wire through the insulator and pull up each section 10 feet at a time and tie off the rope at the base of each tree, etc.

Once you get it up in the air, consider swapping the polarity at the tuner from time to time. The pattern changes - when the band conditions are bad you may see improvements by changing the polarity. I do this all the time.

2234. Balanced line tuner questions

Yahoo group: SkyWires
Date: 2007-03-16 17:12:32 UTC
From: Bruce Conner
Topic: 2234 Message: 2234

Hi,

New to the group, and I'm excited about setting up a horizontal loop for 80-10 meters. Of course, I've got questions!

I'll need a tuner, and I came across this one by Richard L. Measures, AG6K at http://www.somis.org/bbat.html - It's a balanced L-Network that looks good to me. Anybody have opinions on it either way?

For the following proposal, please keep in mind that I'm not planning on running more than about 25 watts, if that. I could live with 10 watts max if it kept the design simpler. I'll be using ladder line, either home made or commercial window line - haven't decided yet.

Assuming the AG6K is a good design, I'm a bit low on nice roller inductors around here at the moment. Some could be obtained (for a price) but I had an idea, and was hoping some of the more expert members here would be able say if it is feasible or not. Would it be possible to make a large slug tuned inductor to do the job of the roller inductor? One of the advantages I see is that the two coils could be put on the same form (well spaced) and the drive could be a single shaft moving both cores in synch. Once adjusted, it should do a good job of keeping things balanced.

My problem is I don't know what I might use for the cores, nor how big the whole setup would need to be. I'm imagining something like 1.5 inch PVC pipe with a core made of balun donuts, driven by a threaded rod. Maybe stack a few of the cores to get length? Could I use a plain brass core to make a gigantic permeability tuner? I've got NO idea how to do the math for that, so any help would be appreciated. I can see that saturation might be a limiting factor, but otherwise it seems like an alternative.

I realize it's sort of a nutty idea, but where's the fun if you can't build something Frankensteinish once in a while? :')

Hi Bruce,

The main idea behind one kind of balanced antenna tuner is to stay with the
concept of a 'Balun', but to put it in the low impedance part of the tuner

circuit... eg next to the 50 ohm coax cable. The article you quote explains very well why baluns don't work well at high impedances where they are inefficient and downright dangerous at high power. The tuner in the article is quite ambitious and not absolutely necessary ... eg using a pair of inductors either switched or roller. It is possible to use a simple L network .... like the small one MFJ sells for end fed wire antennas. It would be modified by isolating the L network from ground ... The balanced line would be connected across the either the capacitor or the inductor and the coax would be fed to the L network via a simple coax choke/balun.

Another very simple but elegant balanced tuner is the venerable Z-match. It is also an L network but with a twist. It does not use a balun, it uses an inductive link coil wound over the inductor. It uses another very interesting 'trick'. It uses a second variable capacitor which is placed in parallel with the inductor. The effect of adjusting the second capacitor is that it alters the effective inductance ! A cheap and easy way to make a variable inductor. By proper selection of component values it is possible to tune a balanced antenna system across 80/40 or 20/10 without switching or actually changing the value of your inductor.

I know it works as I use a commercial version called the KW EZee match. I have very seldom found a frequency/antenna combination it will not tune ... it is fast and effective. There are some articles on the intenet for building one for either high (1000) or low (100W) which are a duplicate of the the KW tuner. There are also some articles on building a QRP version .... same concept.

Google around and I am sure you will find them.

Thanks Jim,

That sounds like it is a torroid version of the Viking Matchbox with the differential capacitor setup. After thinking about it some, I suppose that really is the way to go here, since it will be going on a big loop with balanced line, the "limited" Z that people sometimes complain about isn't much of a factor here. If I'm mistaken, please let me know!

Any particular mods to the Z match that are useful and desirable? Might as well build it right the first time, and I see that people do change them around a bit. 80-20 is probably fine for my needs.

Time to start digging through the junkbox...

From: n6vl
Topic: 2234 Message: 2238

Bruce,

The Measures design is a good design. It is far better than the "balun at the output" designs. I have an MFJ-974H which is a balanced T network, while I think the Measures tuner is a balanced L. Both have a choke balun at the input.

Sorry I can't help you with the balun design.

My balanced tuner of choice is the Johnson Matchbox. But it does have its limitations. The tuning range is limited. I had to move the tap to the input coil a turn closer to the grounded end to get it to match my open wire fed loop, which has low impedances.

One problem with the with the Measures design and similar ones like my MFJ-974H, is that they will not choke off common mode currents on the feed line. I have noticed this on 40 meters. With the Matchbox, I don't get RF into my LCD monitor like I do with the MFJ-974H. My understanding is that the link coupling isolates these currents. I don't remember where I read this. I do remember W8JI stating something to this effect.

I still think the Measures tuner is a good design and I use the MFJ-974H on a 44 foot dipole fed with ladder line, simply because my Matchbox won't tune it.

If you are an ARRL member, check out the article at http://www.arrl.org/members-only/prodrev/pdf/pr0409.pdf on balanced tuners. It was in the September, 2004 QST and a very good article on the subject.

Good luck with your tuner project!

Steve N6VL

2239. Return of the loop

Yahoo group: SkyWires
Date: 2007-03-17 18:30:10 UTC
From: Graham Cooke
Topic: 2239 Message: 2239

Hi,

When I first moved to my new address (7 years ago) I needed a quick to erect all band antenna. Looking through the ARRL handbook I found the loop skywire and with a few old tent poles, a tree and a fishing pole I erected the antenna.

The garden was just about perfect for a 40m loop. I got great signal reports but didn't believe that the antenna could be that good so after 12 months I bought a Hustler 5 band vertical and used a few elevated radials. I made a solid job of mounting it using coax running in a conduit in across the lawn. I was not happy at the performance. Next I tried homebrew single band verticals, then shortened vertical dipoles, then dipoles and finally a delta loop.

Well, I have now gone full circle (actually square!) and rebiult the skywire. Instantly the difference is notable, across all bands I tried! This is a fantastic antenna and I will put a note on the wall not to take it down. If anyone hears me on air contemplating replacing it then please remind me of this post. I feel that I have returned from the rf wilderness.

The loop is 40m perimeter at about 25 feet supported by three fibreglass fishing poles (originally 10m ones but without the floppy top sections) and the wire is 1 mm enamelled copper. Feed is 450ohm ladder line to a Z match tuner.

From: kc0lwn
Topic: 2243 Message: 2243

Is there an optimum length or just use any length as the feed line.

Also I have 2 thousand feet of this stuff, so is it possible to make the antenna by connecting to the outer braid? Or will this be just too heavy and stick with 12 g copper wire?

I will be putting up my first antenna is why I am asking.

I'm sure there are several whom would like to help you. However, you don't give any criteria that is beneficial,i.e.., what frequency/bands, what style antenna(dipole,inv vee, loop), how far is the antenna from your equipment, how much power do you intend to run, is it rg59/rg6 or rg11?.
That being said, you can make a half wave dipole for 80 and 40 and use one coax run. Wire length 136 feet for 80/ 66 feet for 40 meters, run at right angles from center insulator. Coax up to 100 foot of rg59 for 250 watts or less will be good. Put center up as high as possible and ends likewise.
As to optimum length, a halfwave X VF or a even multiple will give you a reflection of the antenna impedance at the feed end. A quarterwave will give you a impedance step-up of down. Anything else is a crap shoot, Though if you desire, you can get an antenna handbook and learn about antennas and then make intelligent decisions as to what you want and desire.

Healthfully yours,

From: kc0lwn
Topic: 2243 Message: 2246

Told you I am new to this. Ok 12 g wire it will be because of the weight issue. The coax is very low loss rg8. I read the article about the German Quad Cloud warmer and they did not specify a feed line length but connected the antenna to 75 ohm coax directly.

40 meter band skywire type of loop is the desired antenna since I want to work 20 meters too. I read that making it 160 or 80 meters would show rapid deterioration at 20 meters. 200 watts power.

It will be about 20-25 feet in height. and the the transmitter will be about 40-50 feet from the antenna. I have an underground conduit to run the feed line cable since the area between the antenna and radio room is mowed frequently and my wife does not want unsightly wires. not to mention my neighbors are already upset about a new ham living next door though they are 500 yards away. The antenna is going to be placed in a windbreak/shelter break that measures about 60x140 feet so it will be somewhat rectangular rather than square mostly. I have very little say in the orientation of the corners. the main restriction is that it must be kept hidden in the shelter belt.

Topic: 2243 Message: 2247

Great. Well, i have a German Cloud Warmer myself. It is a 1 wave length (about 137 feet) loop up about 30 feet on one side and 20 feet n the other side. I use a 25 foot length of rg 6 and then 20 foot of rg58 into the matchbox. I work 40 , 30 ,20 and 15 meters with it using the matchbox.
It is for a second backup rig as my promary antenna is a Carolina Windom at 65 feet and also a GAP vertical. You should have no big problem with 100 watts and the No. 12 wire will be fine for your antenna. I use No. 12 plastic covered house wire for many of my antennas. The RG8X or RG8 will do fine at 50 to 100 watts. Even with the matchbox and non-resonant on all bands i expect 70 to 80 % radiation. Put it up and give it a try. As the old saying goes: anything is better than nothing.

80 good, 160 not so good. A loop resonant at 1.850MHz is resonant at
14.800MHz.

Just calculate the antenna length based on the lowest and highest
frequency you plan to use (it's better to be longer than shorter).

If you run CW on 80, 3.500MHz isn't a bad place to start. 3.500 would
optimally require a loop 287.14 feet long. This length is perfectly
within range for any tuner at 20 meters (14.000MHz). 1005/f = full
wavelength loop length.

The problem kicks in when you cut the loop for 3.700MHz (271.62 feet) and
try to push 20 meters into it. 271.62 feet is optimally resonant for
14.800MHz which becomes a tougher job for your average tuner.

So if you are wanting to put up a loop that is happily tuned on 20 meters
and comfy on 80, divide 1005 / 14.150 and multiply that length by 4.
That comes out to be 284.09 feet.

You can do tricks with lengthening or shortening the ladder line but my
experiences with this is the feedline starts to radiate into things.
Your mileage will vary. There's nothing better than a resonant (or
multiple wavelength harmonic of) antenna.

> It will be about 20-25 feet in height. and the the transmitter will be
> about 40-50 feet from the antenna. I have an underground conduit to run

I've got a 160 meter loop around my property and you can't see it in the
trees. The shiny copper wire is visible when the sun hits it just right.
I used insulated wire - I chose clear but in hindsight I should have
chosen black but I like seeing it.

I would definitely try to cut the wire to a length that is near resonance.
Weird stuff is going to find its way into phones and stereos if there is
swr in the antenna.

that's my 2 cents...

For what it's worth, my loop is up around 30 feet except for one corner that is 15 feet... it handily outperforms my 20m dipole at 38 feet except on the side where the loop is fed. My loop is fed in the middle of the south side and it is a little deaf in that direction. Next fall I will probably move the feedpoint to the north side and see how the DX to the south improves.

2256. 80 Meter loop

Yahoo group: SkyWires
Date: 2007-03-30 14:46:17 UTC
From: Mike Schwendeman
Topic: 2256 Message: 2256

I just put up a 75/80 Meter loop, as a temporary trial for a new radio in my basement. (My main shack is on the ground floor.) My DESIRE is to have the loop usable from 80 through 15 or 10 Meters.

The loop is low, due to the limitations of the lack of towers, etc. It is supported in a three-sided shape at only 15 feet off the ground. It is fed with about 18 feet of 450 Ohm ladder-line (slotted 14 Ga.) that runs to a brand new MFJ-919 4:1 current balun.

The radio is hooked to the balun via coax, through an SWR/power meter.

While the radio's built-in auto antenna tuner is able to achieve a "tune" indication, I am seeing 2.5 to as much as (lots more!) on the VSWR meter.

[1] Should I have NOT chosen a 4:1 current balun? (1:1 is better?)
[2] Should I have located the balun at the feed point, instead of employing the 450 Ohm ladder-line?
[3] Would a 120 foot G5RV be a better choice for this installation? (I could use a pole to support the G5RV at 30 feet.)

Thanks for your help!
-Mike-

Either one is probably okay .... either kind of balun doesn't like to work
at high impedances as you no doubt will experience when feeding the
loop 80/10m ....

>[2] Should I have located the balun at the feed point, instead of
>employing the 450 Ohm ladder-line?

No, you are better off keeping the low loss 450 ohm line ... it has much
less power loss ... especially when dealing with a high SWR.

>[3] Would a 120 foot G5RV be a better choice for this installation? (I
>could use a pole to support the G5RV at 30 feet.)

yes, almost anything at 30 ft will work better than almost anything at 15
ft hi hi .... the advantage of a dipole (G5RV) is that it is very effective
in an inverted Vee configuration, which only requires a single support. I
always prefer feeding such an antenna with balanced line, 450 ohm or 300
twin lead and a balanced antenna tuner ... I find it more effective than
the G5RV configuration ... just my preference.

Topic: 2256 Message: 2258

Mike:

I'm still learning about these "loopy" antennas, but find them to be not only fascinating but very effective as multi-band antennas. My own opinions on your queries:

1) A 1:1 CURRENT balun would have been a better choice if you can't hook balanced line directly to your tuner/matching device. With any large multi-band antenna, you will see a wide range of feedpoint impedances, most of which will be higher than or close to 450 ohms. A 4:1 balun may actually create at some frequencies a very low impedance at the input to your tuner and that's much more difficult to match.

2) There is no reason to put the balun at the feedpoint if you plan to use the loop anywhere it is not resonant...which is an almost infinite number of frequencies! Same thing if you feed the antenna with ladder line. You certainly don't want to use coax to the feedpoint unless the entire run from antenna to tuner/rig is considerably less than 20 feet...or you only intend to use the antenna where it is resonant. I doubt that is the case. The loss in the coax in high SWR conditions will be a problem, even if your tuner seems perfectly happy.

3) You are right that having the loop so low to the ground will make it less than a good performer for DX on 80/75, 40, and probably 30. Even 20 may not be stellar. Having the G5RV at 30 feet might be a better choice for DX on some of those bands. But the G5RV is not an all-band antenna. Depending on design, it will typically perform relatively well on 40, 20, and 17. A longer version might give you some duty on 80/75 and even 160. One advantage of the G5RV is the convenience of having coax as the lower part of the feedline, but that is also a disadvantage. If you are able to tune away a high mismatch on some bands and think you are putting out most of your power, you will be mistaken. The coax is lossy and much of the reflected power is lost as it travels up and down the coax, burned up as heat instead of by the highly desireable radiation resistance.

If you have not been there already, I recommend W4RNL's excellent website: www.cebik.com. I have a diagram and construction details on my own loop at the web site below. I'm still learning on it!

If you could find some way to get that loop up 20 or 30 more feet and feed it to as close to the tuner/rig as you can with ladder line, I think you will be very pleased with its multi-band performance. But try it where it is now. You may be pleasantly surprised or you may

be disappointed, but you will be on the air!

From: Dr.Ace Ratliff
Topic: 2256 Message: 2259

Hi Mike ,
Does the radio have a built in SWR meter ?
You say "The radio is hooked to the balun via coax, through an SWR/power meter."
I say the greater the distance via the coax between the radio and the SWR/power meter the greater the disparity of the 2 "SWR readings". If the radio has a built in SWR meter, go by that reading. The disparity of the 2 SWR readings will vary with the freq.

If the radio doesn't have a built in SWR meter , it is very likely that the VSWR measured at the radio
is less "maybe much less" than at the point of the SWR/power meter.
I'm not a big DX'er but I did have a full wave 160 mtr loop up at 15' feet high and it kicked butt locally.
RF ground isn't always at the ground surface.
Keep in mind that 1/4 ~ at 80 mtrs is about 66' .

Subject: [SkyWires] 80 Meter loop

I just put up a 75/80 Meter loop, as a temporary trial for a new radio in my basement. (My main shack is on the ground floor.) My DESIRE is to have the loop usable from 80 through 15 or 10 Meters.

The loop is low, due to the limitations of the lack of towers, etc. It is supported in a three-sided shape at only 15 feet off the ground. It is fed with about 18 feet of 450 Ohm ladder-line (slotted 14 Ga.) that runs to a brand new MFJ-919 4:1 current balun.

The radio is hooked to the balun via coax, through an SWR/power meter.

While the radio's built-in auto antenna tuner is able to achieve a "tune" indication, I am seeing 2.5 to as much as (lots more!) on the VSWR meter.

[1] Should I have NOT chosen a 4:1 current balun? (1:1 is better?)
[2] Should I have located the balun at the feed point, instead of employing the 450 Ohm ladder-line?
[3] Would a 120 foot G5RV be a better choice for this installation? (I could use a pole to support the G5RV at 30 feet.)

Thanks for your help!
-Mike-

Mike- your feed set up sounds optimal for your situation. I would take the 2nd SWR meter out of line. All you care is that the rig tuner can tune it. (be sure it IS in fact bringing the SWR down, not just trying, and giving up!). My guess is that the low loop would outperform the aforementioned G5RV, but try it, and let us know what you find!!

gud luck.

From: Mike Schwendeman
Topic: 2256 Message: 2262

" I just put up a 75/80 Meter loop, as a temporary trial for a new radio
in my basement. (My main shack is on the ground floor.) My DESIRE is
to have the loop usable from 80 through 15 or 10 Meters....."

Replies to "Jim Dunstan" with my responses:
>[1] Should I have NOT chosen a 4:1 current balun? (1:1 is better?)
Either one is probably okay .... either kind of balun doesn't like to work
at high impedances as you no doubt will experience when feeding the
loop 80/10m ....
=====> OK on this; It is now in place, so this is highly acceptable!

>[2] Should I have located the balun at the feed point, instead of
>employing the 450 Ohm ladder-line?
No, you are better off keeping the low loss 450 ohm line ... it has much
less power loss ... especially when dealing with a high SWR.
=====> Again, OK on this; It is now in place, so this is highly acceptable!

>[3] Would a 120 foot G5RV be a better choice for this installation? (I
>could use a pole to support the G5RV at 30 feet.)
yes, almost anything at 30 ft will work better than almost anything at 15
ft hi hi .... the advantage of a dipole (G5RV) is that it is very effective
in an inverted Vee configuration, which only requires a single support. I
always prefer feeding such an antenna with balanced line, 450 ohm or 300
twin lead and a balanced antenna tuner ... I find it more effective than
the G5RV configuration ... just my preference.
=====> I still have the LOOP in place, as the weather is just too cold
to do any major changing, etc. I HAVE PURCHASED A G5RV antenna. I do
believe I will put this up in place of the loop. Mainly, as the means
of supporting the G5RV will result in a cleaner installation, as the
trees that I now employ as supports are LOW and the wire has to go
around other trees to be even as good (poor?) as it now is.

Replies to "Don Keith" with my responses:
1) A 1:1 CURRENT balun would have been a better choice ...
=====> What I now have will have to do, at least for the time being.
(See above.)

2) There is no reason to put the balun at the feed point ....
=====> OK on this! (Good!) In my case, I have under five feet of
RG-58 coax total, including the SWR meter that is in the coax feed.
(See below for more info on the SWR meter.)

3) You are right that having the loop so low to the ground will make
it less than a good performer for DX on 80/75, 40.... But the G5RV is
not an
all-band antenna. Depending on design......The coax is lossy and much of

the
reflected power is lost as it travels up and down the coax, burned up
as heat instead of by the highly desirable radiation resistance.
=====> Yes to all. Point taken! In my case, the coax is very SMALL,
but it is short, so the loss is at least minimized.

Replies to "Dr.Ace Ratliff" with my responses:
>Does the radio have a built in SWR meter ?
=====> Yes.

>You say "The radio is hooked to the balun via coax, through an
SWR/power meter."
=====> The setup is as follows: The RF output of the FlexRadio feeds a
short (under one foot) coax with PL-259 connectors, to an MFJ (giant
6-inch!) SWR-power meter. The output of the SWR meter feeds a 3 foot
coax made with RG-58 with PL-259 connectors; This 3 foot cable is
directly attached to the MFJ high-power current balun. The 15 foot run
of 450 Ohm ladder line feeds the 1-wavelength loop antenna.

>I say the greater the distance via the coax between the radio and the
SWR/power meter the greater the disparity of the 2 "SWR readings". If
the radio has a built in SWR meter, go by that reading. The disparity of
the 2 SWR readings will vary with the freq.
=====> The SWR indication is accessible in two forms: The radio has a
built-in meter, and I have an MFJ (the new 6 inch peak-reading model)
SWR-power meter.
=====> I am now becoming more "relaxed" at the high SWR indication that
I had described in my initial post. The radio is showing a good match,
as it has a built in auto tuner. The "scary" SWR indications were sen
only on the outboard SWR device. (This is midway between the radio's RF
output and the balun's input.)

>If the radio doesn't have a built in SWR meter , it is very likely
that the VSWR measured at the radio
is less "maybe much less" than at the point of the SWR/power meter.
=====> Yes, for this reason, as well as the fact that the radio's SWR
indication is perfect, due to the built-in auto-antenna tuner.

>I'm not a big DX'er but I did have a full wave 160 mtr loop up at 15'
feet high and it kicked butt locally.
RF ground isn't always at the ground surface. Keep in mind that 1/4 ~
at 80 mtrs is about 66' .
=====> This would be GREAT, but it "ain't gonna' happen" due to my
limited supports that are available.

Replies to "oldlongbeard" with my responses:
> Mike- your feed set up sounds optimal for your situation. I would take
the 2nd SWR meter out of line. All you care is that the rig tuner can
tune it. (be sure it IS in fact bringing the SWR down, not just
trying, and giving up!). My guess is that the low loop would
outperform the aforementioned G5RV, but try it, and let us know what
you find!!

=====> Thank you for your thoughts. Yes, I am now tending to agree with you and the rest of the group that offered their inputs on the matter. I shall remove the outboard SWR meter. What I cannot SEE is OK, as long as the radio is happy! I see normal and full power out of the radio.

=====> As an added FYI, I will tell you that I have a 540 foot loop on the North side of the house; It is at 45 or so feet, and is fed with about 50 feet of 450 Ohm ladder line via an Icom AH-4 auto-antenna tuner. This beast works very well for me! This is one hell of an antenna! (From 160 through 6 meters, it appears.) Now, in this case, I have NO SWR meter in the 12 foot coax line that connects the radio to the AH-4 tuner! (On the SWR indications: What I cannot see, or do not know about is just fine. But, with this antenna, I am not using any balun; The AH-4 serves as the ONLY coupling device, and it is able to tune the loop with ease. The radio's reflected power is zero.)

=====> Also, in view of the fact that I have weak and LOW trees, the NEW 80-meter loop antenna that I have erected is low to the ground, and very sloppy. For this reason, I have purchased an MFJ (groan...) version of the G5RV antenna. I will erect ONE mast made of 2-to-3 inch electrical conduit, telescoped to allow at least a 1.5 inch third, or top section. I will erect the G5RV with this mast. I will disassemble the feed-point's 450 Ohm ladderline to SO-239 adapter, so I can feed the G5RV's ladderline into the house via a hole which is now being used for the soon-to-be-removed 80 meter loop. It is my "plan" to feed about 4 feet of the ladderline into the basement, which is where the present loop's ladderline is terminated with the 4:1 balun. I will add supports to keep the ladderline away from the mast, of course.

=====> Does this sound like a workable alternative? (And, YES; I will retire the external SWR meter...) Thank you, all!! -Mike-

No on that mike replacement, but the one from K9STH Glen Zook works very well. Comments below are from Glen.

The output impedance is 25K ohms. Sensitivity is
rated at -55 dB @ 1000 Hz (1 KHz). Response is 50 Hz
to 8000 Hz (8 KHz).

I am using the element on my boat anchor transmitters
which include Collins 32S-1, 32S-3, Heath SB-401,
SB-110A, DX-100, TX-1 Apache, WRL Globe Champion 350A,
and Hammarlund HX-50A (among others). When compared
with my D-104 that has one of the last D-104
replacement cartridges sold by Astatic before they
discontinued the D-104 the on-the-air reports are at
least as "good as" and often "better than" the
original D-104 element.

Glen, K9STH

2271. Bungee cord size?

Yahoo group: SkyWires
Date: 2007-04-14 00:04:15 UTC
From: Bruce Conner
Topic: 2271 Message: 2271

I'm getting ready to put up my fullwave horizontal 80 meter loop, and I'm planning on using bungee cord for some give as the trees sway. These trees are pretty tall, but they are a little thin, so they do have some movement when the wind blows. I can buy the bungee material off a roll at the sporting goods store, but I don't know what size to get or how much stretch I should allow for on each corner. Any suggestions? This antenna will be up about 30 feet, using #14 wire, and the ususal pulley arrangement.

I'm trying out a new method of getting my lines up in the trees and will report on the success/failure when I've tried it. The initial test went quite well. It's only good for about 35 feet max, but may be good for those of us who can't be running around with bows and arrows, slingshots, or pneumo-canonen. :') And it is super-accurate. The line goes exactly where you want.

BTW, for those of you who want a really good pneumatic launcher design, check this one out: http://users.frii.com/bsimon/pngun.htm I've seen one of these in action, and the internal valving mechanism is FAR superior to using a solenoid or ball valve. Looks pretty easy to make too. Rigged with a tennis ball sized barrel, I could see this being a nice unit in the field.

2272. Re: Bungee cord size?

Date: 2007-04-18 01:58:24 UTC
From: Mike
Topic: 2271 Message: 2272

I'm not sure about bungee cord and I dont have my loop up yet but I do use pulleys,cord and 8 lb weights on each end of a 160M dipole. Last week we had wind gust of 60 MPH+ and the dipole survived fine.My dipole runs through 6 trees so there was lots of swaying going on. I watched one end insulator (the one I could see from the window)move back and forth about 12-15ft. It was a pain to string the dipole through all the trees and I'm glad I took the extra effort to put weights at each end or I'm sure the trees would have ripped the wire apart.

2274. Find your "Radio Grid Square" using your GPS

Yahoo group: SkyWires
Date: 2007-04-21 22:17:33 UTC
From: hastingsji
Topic: 2274 Message: 2274

If you have a GPS unit and need to find your DX "Radio Grid" location there is no need for lat and long conversions, grid maps, etc.

Just go to you're the page of your GPS setup screen, where you choose position format. This is usually something like going to the setup screen, then to units setup, then to position format. Under position format you will change your format form the lat and long format, which may look something like "hadd mn' ss.s" to the "Maidenhead Grid." Now just step outside your house with your GPS and read your "Radio Grid Square" directly from your GPS.

2280. RE: [SkyWires] 1:1 or 4:1

Yahoo group: SkyWires
Date: 2007-04-29 07:22:23 UTC
From: John Farmer
Topic: 2279 Message: 2280

Hello Paul,

I love my loop. I have played around with a number of different arrangements, including various combinations of baluns and feedline configurations.

All I can contribute to your thinking is my own experience.

I have an 80m full wave loop, in the form of a "lazy" rectangle, about 10m above ground.

The final feed configuration for my loop has in fact turned out to be the simplest:

heavy duty, low loss window line from the loop, converting to about 2m of RG213 coax at the entry to my shack. At the transition I have

a choke balun (1:1 ferrite sleeve balun, after W2DU). I connect the coax to the unbalanced input on my autotuner. The tuner can provide a 1:1 match from 80m to 10m.

Perhaps the "ideal" arrangement is running the ladderline directly to a truly balanced tuner, but I don't have one, so this option was out.

With the help of my antenna analyser, I discovered that the impedence at the end of the ladder line at some frequencies was actually already quite low and a 4:1 balun at the coax/ladderline transition did nothing to help this; it just converted an already low impedance to some other (unpredictable) impedance. It certainly did nothing to help the tuner find a better match on any frequency, and I was also concerned about the losses in the 4:1 balun, given that the SWR on the ladder line is quite high on some bands (up to 5:1) and that voltage baluns, especially, are not very efficient as load SWR rises. So I changed to a simple RF choke balun to keep the common mode current off the coax and left it at that.

With this simple arrangement I have had great success with my loop on all bands from 80 to 10m, including WARC bands.

I have no trouble with 80m contacts from Tasmania into the NE of the US and I now have empirical evidence to dispute the often quoted remark that these loops are "cloud warmers" on the low bands at such low heights. The loop also performs well on 20m and have worked 56 countries from Tasmania in 9 months. I've had 10m contacts over 2000km. I run just 100W. If I can hear stations, I can work them and my signal reports are very rarely less than 56. Tuner works fine and I've no trouble with RFI/TVI. Perhaps I'm easily pleased, but I couldn't want for more.

Play with your loop and see what works for you. My only suggestion is to keep the feedline arrangement simple and look to minimize unmatched losses - be careful with your choice of feedline and select a balun which has minimal loss at highish SWR. Perhaps a 4:1 voltage balun isn't the best choice here.

Hope that helps.

73,

John

>Paul

Hi Paul,

The weak point in any antenna feed system that uses a balanced feed line is the transition to the input of an unbalanced antenna tuner (manual or automatic). These ATU's usually come with a ferrite core balun either 1:1 or 4:1. They are satisfactory as long as the impedance of the balanced line (at the frequency of operation) is close to the required impedance of the balun (200-400 ohm for the 4:1 and 50-100 ohm for the 1:1) otherwise the performance (efficiency) of the balun is suspect; this will become immediately evident when you run high power and it goes up in smoke!

Check out VK7JBR's post ... just after yours ... he has made some interesting observations.

So, what to do? Well VK7JBR's recommendation of using an antenna analyzer to actually look at the impedance at the end of the balanced feed line at the point it is to make it's transition is really important ... you will then know what you are up against. Sometimes changing the length of the feed line can bring about a satisfactory compromise on the frequencies you operate. I don't own such an analyzer ... but our Ham Club does and I can borrow it for such occasions.

Another approach which eliminates the finicky ferrite core balun is to use a balanced antenna tuner .... there are a few on the market ... and they are not all that difficult to build .... I personally like the Z-match design.

Another approach .... which I almost never see .... which works perfectly under most conditions ... is to use a standard unbalanced ATU and to keep the frame above ground .... eg .... one side of the balanced line goes directly to the "long wire input" and the other side of the balanced line connects to ground or frame of the tuner. The frame is not grounded in any

other way except via the coax feed line .... and the coax is then formed into a simple choke balun. Such an ATU would be best located outside the operating position and would have to be weather protected. Any of the SGC ATU's work perfectly under these conditions. This approach usually limits power to 100w.

Being a cheap skate at heart .... I have used an MFJ L-network 'long wire' tuner to match a balanced feed line coming into my shack (portable operation).... one side goes to the 'long wire' terminal ... the other side goes directly to the aluminium case, which in turn is screwed to the wood wall. I place a current balun in the coax .... it works perfectly on all frequencies ... I just have to be careful tuning as the small aluminium case is RF hot hi hi!! I have also used unbalanced 'T-match' tuners this way for portable all band operation (greater tuning flexibility than the simple L-match tuner).

In summary, the weak point is the ferrite balun which doesn't like working outside the 50 to 50 ohm or 50 to 200 ohm ranges. Solution ... don't use them except for conditions falling into these ranges ... check it out with an antenna analyzer. If you find one or two problem points ... changing the feed line length (adding in a piece of feedline) may be the solution. If you are going to use a manual TU then go for a one designed for balanced feed line. If you want to use an unbalanced ATU ... then isolate its frame from ground and put in a current choke/balun on the coax.

Jim, VE3CI

Paul,

I have just recently gotten my loop working, and I have to say it is great! But I did have some obstacles to overcome which perhaps may be useful here.

I'll skip all the parts that did not work, and try to get straight to the point of what actually works for me. My loop is 160m, is level, and is 30-50 feet up in the air as the land goes up and down under it. There were many combinations that were suggested that simply did not work. I was considering changing to 450 ohm window line, when a friend loaned me his antenna analyzer. I got up on a ladder and connected it directly to the loop. I WAS AMAZED! Instead of checking SWR, I checked for resonance points (using the Z/Theta method). As predicted, they occurred near 160, 80, 40, 20, *12*, and 10. I don't know where the 12 came from, but I was ignoring the bands and just going for the resonance locations. I looked at the impedance at each of these resonant points. The loop's impedance at resonance varied from 8 ohms (10m) to 129 ohms (80m). It was actually lower at 160m, but I don't have the impedance information with me right now. 8-129 ohms! Obviously, there was no way to match a feedline. The previously poor performance was explained by the fact that no single balun, feedline, or stub can match the loop impedance correctly unless I give up and use it on only ONE band - no way!

I believe a balun is useful to isolate the RF currents and transition between the balanced loop, and the unbalanced feedline, so I went ahead and put a very well built balun at the loop transition. Next I bought an LDG Z-11 Pro smart auto tuner and put it right at the feed to the balun. Then I ran a 145 foot garbage coax back to my rig, where I run as much as 100W. I chose the Z-11 Pro because it has excellent reviews on eham, is very cost effective, requires no extra wires - it simply detects a high SWR, corrects it, and stores the result in memory even if I tune up using SSB.

I've only had it up a few weeks and have checked into a regional SSB net on 80m a few times. I'm in Atlanta, Georgia, USA. During the regional net I can hear every single station that checks into the net from Texas, Mississippi, Missouri, Ohio, Arkansas, Kentucky, Alabama, Virginia, Florida, the Carolinas, and Tennessee where net control is located. Most stations peg my S meter (>S9+60), and all are over S7. Net control informs me I am "loud and clear". In my few weeks of tinkering with it, I have made a contact in Wyoming on 40m SSB. He reported a "clear strong signal" to me, I think he said S6, but I neglected to write it in my log - hopefully I'll get a QSL card. That's a distance of 2539 km or 1578 miles.

Here is why I believe my loop works so effectively in a somewhat different configuration than is commonly recommended. First of all, at HF frequencies, even garbage coax doesn't have a great deal of loss, as evidenced by the consistent pegging of my S meter with crystal clear signal with my preamp off. It WILL have a great deal of loss if there is an impedance mismatch between the coax and the load (like when the tuner is in the shack). In general, the more mismatch you have between your coax and your antenna, the more loss you will have in the coax. Second, most importantly of all, the tuner needs to be at the load (the antenna) or it will do nothing but match the poor system to the output impedance of your rig or amplifier. When you use a 4:1 balun to connect an 8 ohm load to a 450 ohm feedline which goes all the way back to an antenna tuner in your shack, you have nothing but losses, reflections, and an inefficient setup. Sure the tuner will get your SWR down so you can output full power from your rig, but you are most certainly not getting the power into your loop effectively. Many people have gotten this to work and I attribute that to the wonderful characteristics of the loop itself. And finally, use a balun at the transition. I feel like a "real" transformer balun is better at matching the loop to the tuner than beads around the coax or loops of coax, but that's just an opinion.

Anyway, going from the loop to the rig, the loop has some given impedance at some frequency, it goes from balanced to unbalanced with a slight loss, then immediately into the tuner (really more of a transmatch here I suppose), and then travels happily matched along the 50 ohm feedline back to the rig. I always have 1:1 SWR at the rig. The system works so well that I tuned it up on 6m and made some local (no skip) SSB contact with it on 6! I have even used it to check into a 6m FM net where the repeater is about 20-30 miles away - that's just all wrong, but it worked! I have used it on 10m and 20m successfully too.

I really want to make some contacts on 160m, but the band has been so hot and cluttered lately, that I haven't been able to find room to call CQ. On 160, I literally cannot move my tuning dial without hearing another conversation and the meter stays pegged from end to end. I have even listened on 160 with the rig's attenuator on, which is something I NEVER thought I'd have to do with a 145', crappy, coax feedline.

Just for one last note, with all else being the same, when I use a tuner at the rig, I can match the feedline to the rig, but I get worse receive performance, and nobody can hear me. Strong stations are more like S5-S7 at most.

Are there other ways to do it? Certainly! I do not mean to say that other advice is not good, or that there are not other ways to successfully install a loop skywire. I am just elated about how mine works now that I have worked out the kinds, and felt I should share my recent success with the group.

Hope to work you all on the air!

Kyle,

You didn't mention what type of balun you used ... voltage or current;
4:1 or 1:1; manufacturer (or home brew)?

Kyle,

Very interesting and encouraging, I've had similar plans here. If you
don't mind my asking, what steps did you take to weatherproof your Z-11 Pro?

Erik,

I am running the Z-11 Pro off a battery pack that connects to the external connector. I didn't put the batteries inside the case like the manual says you can. Let me say, this has been an evolving project with a great deal of learning involved on my part. Right now the tuner is just out there and I go up and down the ladder to get it out of the weather (not great).

It is a tiny tuner, so this weekend's project will be to put it in an "ammo box". They are sealed, hardy, and cheap here. I'm going to put the battery pack and the tuner in there, and have two SO-239 "bulkhead" connectors for the feedlines. According to the manual, the batteries should last a long time, so perhaps I'll have to go up there about once per year to change them. I can live with that.

The corner of the loop is attached to the roof of the side of the second story of my house, and I plan to attach the ammo box to the wall. I have not decided which method I want to mount it with, but I will paint it to match the house when I'm done so it won't be such an eyesore.

2295. Multiple wave Loop

Yahoo group: SkyWires
Date: 2007-05-11 03:33:31 UTC
From: n7cal
Topic: 2295 Message: 2295

I am putting up a 4 or 5 wave length loop and wanted to run some stuff by the group.

First the wire: I am using seven strand aluminum power line. It's about 3/8" in diameter.

I will be putting it at an average of about 60 to 80 feet up using trees and power poles.

I will be using 450 ohm ladder line from the antenna to a polyphaser and balun just outside the shack, then about 10' of coax to the tuner.

Any concerns or input? I did see where the use of a 1:1 balun is preferable to the 4:1. I will be running a single 3-500z amp so I dont want to risk a hot spot. I live on a 25,000 ranch and dont get to town for supplies very often, I have a 4:1 balun, will this work ok?

Has anyone ever put up a multiple wave length loop? should I worry about cutting it to a multiple of my favorite 75 meter frequency? Has anyone ever had a multiple wavelength loop that didn't require a tuner?

Thanks
N7CAL

A friend of mine, AL7KT, threw a loop of wire over the roof of his apartment. I was there to help and to see the test of the resonance. It was either an 80 or 160 meter loop, but I believe it was 80 meters. He used copper wire laying on the shingles of the roof and fed it with 300 ohm window-line. Two stories below at ground level, he tapped it with a 1:1 balun and fed the radio with about three feet of RG-8. His first layout produced a low SWR on 80 meters and it was a little out of the bands for several HF bands. However, he trimmed it a little and wound up with an antenna that worked five or six bands without a tuner and the rest of the HF bands with it. (I don't specifically remember the 160 meter band, but I remember his great interest in it.)

Al worked with very many loop antennas and rather than measure with a measuring tape, he estimated it's length in the beginning. Once he got resonant frequencies, he fine tuned it by trimming what he needed to make up

the frequency so the exact length of the wire is not known. He is a little illusive, but you may be able to contact him with information on QRZ for more details.

I think to answer your question, if his (80 meter) loop worked on several bands, your multi-wavelength should work as well.

I have heard chatter on the antenna groups to the effect that multi-wave loops do not perform as well as full-wave loops. You will have to look into that on your own.

I wish you well and hope it works.

Hope to see you on the air.

Multi wavelength for what design freq? Of course it will be multi wave for any higher freq. A multi wave loop begins to sound like a shorted rombic without termination. I guess it depends on the shape and where you feed it.

My one caution is to be sure that you take into consideration the build up of a static charge on the antenna. This is especially important in dusty or semi-desert areas. An antenna that large is also subject to precipitation static. One way to bleed the DC charge off is to run a high ohmage resistor(s) to ground. These were built into the TMC RAC termination and coupler boxes used by the military at their HF receiving sites. (TMC = Technical Material Corp, Mamaroneck, NY / RAC = Receiving Antenna Coupler) This is not lightning protection. Lightning will destroy the resistors. My antennamen took daily resistance checks to make sure they were still good. The resistors will have no appreciable effect on the impedance, gain, or pattern of the antenna.

Craig,
End fed wire and/or loop antennas can develop very high static voltages on them.
This static voltage can easily be high enough to knock the front end out of sensitive receivers.
One method to overcome this problem is to connect a resistor from the coax center to shield (if you use coax) where the antenna wire connects to the coax or across a parallel feedline.
Only use a non-inductive resistor, carbon resistors work fine.
Don't use wire wound or metal film resistors.
The resistance value is not critical. The resistor can be left in the circuit at all times and will have no measurable effect on VSWR , power loss , etc.
I suggest about a 56K ohm 1/2 watt resistor for receive only or if transmitting with up to 100 watts.
If you will be transmitting with high power "QRO", I suggest using about a 1 Meg ohm 1/2 watt resistor.

Hi Ace,

Just some further comments on your suggestions for high static voltage prevention:

I agree with the resistor across the gap between the coax shield and center conductor for mono pole type antennas such as long wire and vertical antennas as well as directly fed dipoles .... this will provide a DC route for static to drain away to ground from all parts of the antenna.

Any loop antenna that is directly fed with coax already provides a DC route for static currents from all parts of the antenna .... placing a resistor across the coax in this situation is redundant. If the loop is fed with a balanced feed line then there are several different possible situations. At some point the balanced feed line must connect either to a coax line or an antenna tuner. If it connects directly to a coax line followed by a simple current balun (coiled up coax) then the situation is identical to the direct connection mentioned above (no problem). If it is

connected to coax or an antenna tuner via a balun wound on a ferrite core, either 1:1 or 4:1 again there will be direct DC connection to the coax shield and a resistor would be redundant.

Twin coil balanced antenna tuners (double L netork) also provide a DC connection to ground for the whole antenna (if it is a loop). The only situation I can think of that will leave a loop antenna above DC ground is when the balanced line goes directly to a link coil as is the case with the Z-match antenna tuner circuit. Placing a resistor across the feed line will not drain the static voltage to ground and it will be possible to draw a static arc across gaps to the receiver input.

In this case the only way to drain static DC voltage buildup to ground is to either provide a center tap to ground on the link .... or provide a pair of high value resistors to ground on either side of the link (in the interest of balance). The old style antenna tuners usually used the DC center tap technique.

Under certain circumstances it is certainly worth the effort to provide a DC connection to ground. I have seen conditions with wind and either rain, snow, or blowing dust where long wire antennas will draw an arc at least 4 to 6 inches !! I have seen 2" arcs from a 20M quad loop (only 70 ft in circumference) fed with 72 ohm balanced line. You wouldn't want that at the input to your receiver!

All,

I think that connecting a static charge bleed-resistor _across_ the
feed-line will not solve the problem, since the loop itself is already a
direct 'short' to the DC static charge that's building up on the lines.

We actually want a high ohmage bleed resistor wired from either leg of
the loop to earth ground, to bleed off the static charge, no?

Craig,
Yes the resistor is there always, and is continually draining off any static buildup. The antenna couplers did include an air spark gap in addition to the resistor. This was in the 60's & 70's (maybe before polyphasers) and all our receivers had tube front ends (R-390's and such). Our rombics were designed for low HF (3-6 or 4-8 MHz), were 3 or 4 WL, and were usually at 90 or 120 feet and would work up into mid HF. Some were tilted. I think the resistor in one model of the coupler was 1 Meg Ohm.

The ARRL Handbook (antenna chapter) and their Antenna Book are good references. http://www.arrl.org/catalog/ Most of their other antenna books are a subset of the above or may include more examples of specific types.

Jim ,
I agree with everything you said. A resistor across the feedline should make no difference on most loop antenna installations. Very high static voltages can build up on large antennas. Also very high pulse voltages can be induced by lightning strikes within a few mile range.

Only use a non-inductive resistor, carbon resistors work fine.
Don't use wire wound or metal film resistors.
The resistance value is not critical. The resistor can be left in the circuit at all times and will have no measurable effect on VSWR , power loss , etc.
I suggest about a 56K ohm 1/2 watt resistor for receive only or if transmitting with up to 100 watts.
If you will be transmitting with high power "QRO", I suggest using about a 1 Meg ohm 1/2 watt resistor.

Hi Ace,

Just some further comments on your suggestions for high static voltage prevention:

I agree with the resistor across the gap between the coax shield and center conductor for mono pole type antennas such as long wire and vertical antennas as well as directly fed dipoles .... this will provide a DC route for static to drain away to ground from all parts

of the antenna.

Any loop antenna that is directly fed with coax already provides a DC route for static currents from all parts of the antenna .... placing a resistor across the coax in this situation is redundant. If the loop is fed with a balanced feed line then there are several different possible situations. At some point the balanced feed line must connect either to a coax line or an antenna tuner. If it connects directly to a coax line followed by a simple current balun (coiled up coax) then the situation is identical to the direct connection mentioned above (no problem). If it is connected to coax or an antenna tuner via a balun wound on a ferrite core, either 1:1 or 4:1 again there will be direct DC connection to the coax shield and a resistor would be redundant.

Twin coil balanced antenna tuners (double L netork) also provide a DC connection to ground for the whole antenna (if it is a loop). The only situation I can think of that will leave a loop antenna above DC ground is when the balanced line goes directly to a link coil as is the case with the Z-match antenna tuner circuit. Placing a resistor across the feed line will not drain the static voltage to ground and it will be possible to draw a static arc across gaps to the receiver input.

In this case the only way to drain static DC voltage buildup to ground is to either provide a center tap to ground on the link .... or provide a pair of high value resistors to ground on either side of the link (in the interest of balance). The old style antenna tuners usually used the DC center tap technique.

Under certain circumstances it is certainly worth the effort to provide a DC connection to ground. I have seen conditions with wind and either rain, snow, or blowing dust where long wire antennas will draw an arc at least 4 to 6 inches !! I have seen 2" arcs from a 20M quad loop (only 70 ft in circumference) fed with 72 ohm balanced line. You wouldn't want that at the input to your receiver!

Hi Bill,

You are correct, I think I was trying to say that placing a resistor across the feed line does not provide a DC short to ground to drain off static charge. I was also trying to say that almost all methods of coupling to a loop ... whether it is direct coax connection or via a ferrite balun will automatically provide a DC connection to ground. The only way a loop will become isolated from DC ground is to couple a balanced feed line to an RF transformer link as in a Z-match antenna tuner. That problem is solved by either grounding the centre of the link coil or placing high value resistors from the feed line (one on each side to maintain balance) to ground.

It seems to me that if a loop antenna was connected via coax (no balun) directly to an ungrounded radio, that the only way any static build up could bleed off would be thru the receivers front end.

Hi,

Well if the coax shield is DC connected directly or indirectly to a loop, the front end components would be at about the same DC potential as the coax shield/radio case. If there is no DC connection between the radio case and Earth ground (either through the electrical system or a specific ground wire attached to the radio case) the radio case/components will rise to the same static potential as the wire antenna. The front end components would not be in danger as the route to ground would more likely be through the power supply route ..... or through the operator!

Here is the rundown on how I am going to set up my loop. If there is anything objectionable here then let me know.

1: 4 wave lengths of the seven strand aluminum power line wire
2: 450 ohm twin lead, 65 foot or so
3: 1:1 balun
4: spark arrestor (polyphaser or MFJ 272) grounded to independant ground from radio
5: 10' RG-8 into the shack to the tuner

I'll tell you, opinion begat opinion.

I appreciate the input guys, I should have asked for the simplist form of getting the job done.

One other question, on a true loop, would not a resistor grounded off one leg of twin lead effectively be connected to the other as well?

2312. zepp instead of a skywire

Yahoo group: SkyWires

From: Clinton Stockton
Topic: 2312 Message: 2312

I just moved into a Manse at Andrews Presbyterian Church in Andrews, SC.
I was hoping to put a large skywire, but once I got here and considered
all my options I could not put up a 280 foot loop.

I don't have a modeling program, and I think I worked out what might
work on 80-10.

An end fed 1/2 wire for 180, 135 feet and fed with 65 feet or 450 ohm
ladder line. If my memory serves me well I should have a low impedance
match on 80, and on 40 it should match and keep low.

Had anyone fed a 135 foot wire from the end with 65 feet of ladder line.

My tuner is an MFJ 974HB.

Thanks for the help

Hi Clinton,

What you are describing is a 'Zepp' antenna. I have used one once for 40M, configured as you described .... 1/2 wave wire fed from the end of a 1/4 wave 450 ohm (actually I used 300 twin lead) balanced line. It indeed presents a relatively low impedance at the feed point. I used a simple balanced antenna tuner between the radio and the feed line. However the antenna does not behave the same way on harmonics ... eg 40-20 or 80-40.

In your example of an 80M Zepp the 135' top wire does represent a high impedance at the ends on 40 as well as 80. However, the 65' feed line represents a low impedance at the feed point end for 80M but a very high impedance at 40M .... it could be tricky matching it .... especially at higher power.

This all 'looks good' per my floundering. (I have erected loops with no POSITIVE way to do a task, such as the choice between coax and ladder-line (ladder-line seems to be the most popular).

In my case, I feed my present loop with ladder-line directly attached to my Icom AH-4 tuner; This seems to do a tremendous job in overall performance. (I must say that I have found NONE better; I have tried a LOT of tuners, tried the balun/no balun issue, feedline choices etc.)

On your four-wavelength antenna: I had more than 2000 feet of #14 THHN copper wire in the air. (-Tried steel electric fencing, before that...) -The old guys said I'd wind up with a 1-wavelength as the BEST size, but 'I knew better...') Well, I kept trimming this thing back, more and more; I now have a 1-wavelength loop that does it all WELL. So, in MY CASE, I endorse the 1-wavelength loop, but your installation may allow a better signal than mine did. -Just offering my findings, not anything close to the absolute 'way thou shalt erect a loop' rule.

>
> One other question, on a true loop, would not a resistor grounded off
> one leg of twin lead effectively be connected to the other as well?
>
This (and all of the other comments that effectively agree on this point) is good, and is correct. However... If one leg OPENS at the feed-point, the DC path is no longer in place this feature is no longer in place. (The ladder-line can and does open, in some installations!) So, a token 100K resistor-to-ground on both legs of the ladder-line is an easy and low-cost piece of insurance that guards against the possible static buildup.

Clinton, you should be able to use the endfed 135 foot on
160, 80 ,40,and 30 with good results. 20 and above will be
directional off the end of the wire. You may have to add a
length of feed line to get reasonable match on 40 meters
as the impedance should be high. I have a similar antenna
178 feet long with 70 feet of 450 ladder line and it works well.

Healthfully yours,

Hi,

You're right - got a direct connect around the loop.

Dr. Ace's web page also has a cool easy to make 4/1 balun that is intended to be grounded and offers the low resistance approach to keeping wind generated static down. It's made from pvc pipe and electrical wire. I've made one for a portable loop where it goes from 50 ohm coax to a 30 ft section of 450 ohm window line up to the loop.

If you hook a little neon bulb between the antenna and ground, it will discharge static, AND you'll be able to see how much static tends to build up in the antenna. It's quite something to see. Distant thunder and your little bulb blinks away at you.

Someone here may have more insight on how effective this is at draining the charge - I could see that some amount of voltage would have to be built up to get the bulb to fire, as opposed to using a resistor which would drain all the time. I've never had a problem with this setup, but maybe I've been lucky.

Bruce,

How much power are you running? And, any idea what's the worst-case SWR
at max power? (of course, this is frequency dependent ... do you have a
reasonably accurate SWR meter on the line?).

Depending on the power/SWR combination, you may be building up some
very high voltages during TX, which may fire the neon bulb.

Or, do you disconnect the neon bulb while transmitting (didn't sound
like it from your writeup).

OK, heres the setup.

After I get the wire up, which should be this weekend I will put one K-ohm 1/2 watt per leg to a ground away from my radio, amp and tuner ground. this will come off my ladder line prior to a balun that will allow me to connect my coax that will get me into my shack which is in the basement.

Now my setup: TS 930, AL80A Amp, ATR15 Tuner, approx 1KW out

Recap:

1: 4 Wavelength #4 aluminum 7 strand power line wire
2: 65' 450 ohm ladderline with twin resistors to independant ground
3: Balun
4: 10' RG-8 into shack

Thanks to all

Bill,

Yes, sorry, Rx only or in "safe" mode with the neon bulb, otherwise you may have a very short, but well lit transmitting antenna! I mainly use it to get an idea of how much stray charge is floating around out there on the wire. It's a good indicator, and it also impresses the non-technical folks.

Hi,

You seem to have 2 questions ... the first being: is it possible to put an unbalanced tuner directly at the feed point of a loop (balanced antenna). Yes, it is certainly possible. The second question relates to how you should ground the tuner/coax/rig. The second part is confusing since you mention the tuner and rig being 6' apart ... i assume this is a different arrangement having nothing to do with the first question.... where the tuner is at the antenna feed point.

If you put an unbalanced tuner (automatic tuner is the rule) at the antenna feed point .... it will be connected to a coax feed line which will provide a DC connection to ground via the shield. However, it will also provide an RF connection to ground via the shield .... which is not what you want; you don't want the feed line to be part of the antenna and you can do without having RF in the shack. To prevent RF on the outside of the shield it will be necessary to place an RF 'choke' on the shield as close to the ATU as possible. The choke can be made from ferrite beads threaded on to the coax (commercial versions are available) or simply winding about 20 feet of the coax into a tight coil as close the the ATU as possible. This will work with any antenna fed with coax.

In a properly designed antenna/feed line system that uses coax .... the ground at the rig should ideally be for DC ground for safety of both the rig and the operator. There should be little or no RF on the outside of the shield.

2330. Static Build-up - ouch!

Yahoo group: SkyWires
Date: 2007-05-19 17:58:30 UTC
From: Graham Cooke
Topic: 2330 Message: 2330

Hi all,

After reading the thread on static build-up I had personal and rather frightening experience of it this afternoon. I have a 40m full wave loop at about 25 feet, supported by fibreglass poles. The feed is 450ohm twin to a Z match tuner (no dc path to earth).

The rig has been monitoring for low level QRSS signals all day and I was aware of a clicking sound coming from the tuner. It sounded like the tuner was arcing over and so stupidly I disconnected the feeder - BAM! I got one hell of a belt from it! I reconnected it and looked round for something safe to ground it to, disconnecting the rig to protect the front end. At that point sparks flew all over the desk, the cmos keyer started up, the computer rebooted and the rig flicked to TX. All very frightening.

I looked at a web page that shows lightning storm distribution and nothing was showing.

http://www.meteorologica.info/UK6lightning.htm

A quick look out of the window revealed a dark cloud. Once the cloud had passed the static stopped. Needless to say the loop is now tied hard down to ground!

What do others do to prevent this kind of event? I was thinking of winding a large inductor but there are high voltages present during transmit and so it would require substantial insulation on the turns.

When I fly my kite antenna I always take static very seriously, but now I will be taking it seriously at home.

Hi Graham,

In one of my recent posts concerning the build up of static voltages on a
balanced antenna I pointed out that almost all systems will provide a DC
path to the frame of the rig (everyone should have a simple ground
connected to the rig). This DC ground is via the shield on the coax and
the balanced feed line has DC connection to the coax via balun or
tuner. The exception are antenna tuners that use link coupling .... just
like yours .... a Z-match design ... (you probably use a KW-Ezee

tuner). The solution is to either provide a DC connection to ground at the center of the link coil .... or to provide high resistance carbon resistors connected from either side of the link coil to ground. I have never seen this in any of the many online articles on Z-match tuners. However I have them wired into my KW-EZEE match and they work just great, gently draining these static build up voltages to ground .... with no affect on operation.

However, I can't stress enough the need to shut down the station and provide an effective ground for all antennas and the rig front end when those big black clouds come into view.

Topic: 2327 Message: 2332

Back in College in 1959 I had a HRO 5 receiver and
600 watt Temco transmitter feeding a long wire about
300 foot long. I hung a 4 foot florescent lamp tube at
the end of the wire and at night I could tune for max
brightness. Campus police investigated the reports
of UFO sightings by neighbors. They were happy there
were no UFO's. And interested when they had opportunity
to participate in chatting from Southern Ohio to California
on 80 AM.

Healthfully yours,
Don W4BWS

Topic: 2327 Message: 2333

Bruce, the neon bulb at the receiver antenna terminals
is good for high levels of voltage such as with a long wire
into a high impedance antenna input. However the neon
requires from 45 to 60 volts to fire depending on the type.
Therefore, a lot of voltage can appear across the input
before the neon fires. Also if you are using a low
impedance antenna input, the neon may never fire.
Back to back diodes work much better on low impedance
antenna inputs.
Back in the 40's and 50's many used longwire receiving
antennas, thus the neon's worked well. During WW2 the
airborne radios used trailing wire or short endfed wire
antennas and the receivers had neon's across the
antenna inputs. Good for their time, but not so good now.

Healthfully yours,
Don W4BWS

Bill,

Yes, sorry, Rx only or in "safe" mode with the neon bulb, otherwise you
may have a very short, but well lit transmitting antenna! I mainly use
it to get an idea of how much stray charge is floating around out there
on the wire. It's a good indicator, and it also impresses the
non-technical folks.

I used to run the SGC mounted under the eves of the house at the 2nd story peak and tied to a loop that ran around the house under the eves. I worked a lot of DX as well as state side stations on 80 thru 10. I worked lots of stateside on 160 out to about 1500 miles. This was when I lived in Florida- I moved to Alabama 3 years ago and have 70 foot pines now to hold the antennas. I grounded the coax at the entry to the house but the tuner was not grounded otherwise.

Has anyone had any experience putting an
upbalanced tuner such as the SGC-230
http://www.sgcworld.com/230ProductPage.html
or the ICOM AH-4
http://home.comcast.net/~hamlakemn/ah4/ah4.htm
directly at the feedpoint of a horizontal loop?

If so, would you ground the tuner or ground the rig or ground both,
if they were about 6' apart, with the rig inside the house and the
tuner just outside the house?

If ground both, what would the topology be? Two home runs to the ground rod?

Hi Pastor Don,

Was wondering if you tried a 40 meter loop. I believe I can put one up and use it for 30 and above, and occassionally on 40. I have seen several formulas for cutting the loop. 1005/f 984/f 120/f and even 130/f. I really would like to know what has worked best for others. My MFJ-974HB seems like it will tune almost anything, but I would rather have the Loop close to what it should be.

thanks and 73's

HI, well, I currently have a 138 foot loop up about 30 feet and I use it on 40 thru 15 with the tuner. It is NVIS on 40 and 30 but I have worked some DX. The normal formula for a quad loop is 1005/f for 1 wave length. However I found that I had to shorten it slightly to get the best match. I used a quarter wave of RG6 then RG8X into the shack to the tuner. It does not do as good as the 80 meter Carolina Windom but does better on 40 AM for local and regional signals. So I would say try it and see. I use it for the second receiver when not being used for a QSO. I am fortunate to have the loop, a GAP Challenger vertical and Carolina Windom that I can switch between to get the best signal. Let me know how you do.

I will try and put up a loop this week.
I basically walked off an area and found I can do it with an attachment on the chimney, and two trees.

Your 138 ft comes in at 7.1 mhz using the 984/f which I think is the cutting formulat that Cebik uses.

I can get my loop with three sides all being 46 ft each and I am going to feed it with 450 ohm ladder line. I will let you know how it works. The tuner here is a MFJ 974HB Balanced tuner.

2343. End Fed Zepp Question

Yahoo group: SkyWires
Date: 2007-05-21 14:10:15 UTC
From: Clinton Stockton
Topic: 2330 Message: 2343

I have a question concerning 135 foot end fed zepp with ladder line.

I am using about 67 feet of ladder line and I am able to tune it and get a low SWR on 75 and 40 meters. It basically does not tune on 80 meters or 3.8 to 4 mhz.

My manual that came with my MFJ-974HB says the best match occurs with Max capacitance on the TX and ANT adjustments and for minimum Inductance.

On 75 I am using a lot of inductance, Letter B on the tuner with the TX capacitor being mid range and Ant capacitor between 1 and 2.

On 40 my TX capcitor is moving towards minimum capactitance with a number of 8 or 9, the Antenna Capacitance is between 1 and 2 and the inductor on C.

Has anyone out there played with the end fed zepp of 135 feet and determined what the best feed line length is. My tuner is supposed to tune anything between 12 and 2000 ohms.

Thanks

Paul,

My 160 is fed with 145' of coax, to an LDG Z11 Pro and a true transformer balun, right at the feedpoint. Before choosing this arrangement, I put an analyzer on the feedpoint of my loop and found the impedance changes from 8 ohms to 129 ohms depending on the band. It only makes sense to put the tuner at the feedpoint once you know this, because there is no combination of baluns or tuning stubs that can make that range of impedance match any feedline (unless you only want to use it on a single band).

This setup works extremely well! :)

Right now, my tuner is not grounded except through the coax. Soon I plan to ground the tuner remotely and tie the loop to the same ground through a 1M resistor (electrically in parallel with the balun). This should bleed off wind induced static, but allow the RF to see the loop as a balanced antenna fed from an imbalanced tuner.

Topic: 2330 Message: 2345

A zepp antenna is mono-band... Your antenna length is 135 feet, which makes it an 80 meter antenna... The quarter wave stub, at the end of the antenna, changes the waveform from high voltage / virtally zero current, at the end of the antenna to high current / virtually zero voltage at the end of the 67 foot quarter wave transformer....

The zepp antenna, looks like a dipole antenna, at the non-antenna end of the quarter wave stubb...
So if you connect your coax to the quarter wave stubb and feed that to your radio, you should have a good match....
If you are connecting your ladderline directly to your coupler, then tune for best responce....
If you are tuning it onto, lets say, 40 then you are .. converting .. your antenna to a, essentially, random wire antenna....

>73 Clive G8POC. Oxford, UK.

Hi clive,

I don't have the SEM Transmatch circuit in front of me .... however, if it is a version of the Z-match circuit the antenna input connects to a link coil. If the input is unbalanced such as a long wire antenna or coax then one side of the link coil connects to ground .... in this arrangement there is no problem with build-up of static voltages as they are directed to ground via the link coil. However, if you feed a balanced line to the tuner then each side of the balanced line connects to each side of the link coil with no connection to ground. As the person posted on this list ... this can, under some environmental circumstances, lead to build up of a high voltage static charge with arcing in the tuner.

In the majority of cases when using a balanced feed line the objective is to feed the doublet or loop on multiple bands with the result the tuner will encounter a variety of impedance values from as low as 30 ohms to as high as 6000 ohms. The resistor or resistors should be a high value such as 100K to 1meg. It is possible to use a single resistor connected from either side of the link coil to ground .... and it will have little effect in interaction with the load impedance. If you use 2 resistors .... one on each side of the link, they should be the same value. As far as current rating simple 1/2 watt ratings should suffice, you can use 1 watt value to be sure ... but be sure the resistor is a carbon resistor and not wire-wound. In practice the resistor will provide a slow 'bleed' of high DC voltage to ground .... as long as the feed line provides a reasonable impedance .... eg 5K or less .... there should be little if any interaction with the transmitter power.

Jim, VE3CI

Hi Clint,

The end fed Zepp antenna is a 'finicky' arrangement. Finding the 'sweet spot' even on the band for which it is designed is tricky at best. From what you posted, you hope to have 80/40M coverage, and so far you have 40m and 75m coverage. However, you tuner is unable to handle the impedance as you go lower in frequency ... eg 80m eg the impedance moves outside the capability of your tuner. The alternative is to adjust the length of either the 135' antenna or the 67' feed line.

Adjusting the feed line is the easiest option .... (you don't want to lose the 40M function) ... try increasing or decreasing the feed line length by 10'. By adding or subtracting a piece of feed line you may be able to get 80m. Once you find the solution you can devise an easy method of adjusting the feed line length ... with a plug or switch arrangement. If you are 'lucky' you may find a compromise feed line length that puts all of 80/75m and 40m band within the tuning range of your tuner.

Thank You Jim, VE3CI

I do have a closet I can hide loops of ladder line in. Do you have
any guide lines on large to make loops and how far apart, or is that
just trial and error. The closet is 2' x 2' and about 4' high.
Once I get the right lenght, or end up having to do switching I can
close the door to cover the large loops of ladder line.

Thanks again Jim and 73's

Personally, I would not loop.. loop of ladder line in a closet...
The idea behind balanced feed line is to cancel out rf noise as it passes
by the feedline... By wrapping it up in a bundle, you are defeating it's
purpose...

Hi Clint,

You are right ... it is mostly trial and error. I recall years ago making a feed line 'adjuster' in my Grandmother's basement .... I installed two pairs of 10' parallel copper wires from the basement rafters. I then used clips to adjust feed line length hi hi. The end fed Zepp is primarily a single band antenna and with dimensions you have used it will be most effective on 80/75m.. I suspect you won't need too great an adjustment to bring it range for 80m operation. Try a few feet at a time.

Hi Clint & Ace:

W5DXP's approach to tuning the line is similar to the way I used to tune parallel lines many years ago ... instead of connecting directly to coax and using an RF choke (the RF choke is a good idea in any event) I used a balun (made from air-dux coils) which could be switched from either 1:1 or 4:1 arrangements. Instead of knife switches I used simple banana jacks and plugs. Not exactly fast QSY ... but I used xtals in those days hi hi .

Hi Larry,

Yes, I agree with you ..... in that an end fed Zepp only performs like an end fed Zepp on the design frequency, in this case (135' wire fed by 65' feed line) 75/80M. If your antenna tuner loads on other bands the whole antenna/feed line is acting as a long wire antenna .... eg the feed line will radiate as well as the top wire. Getting an end fed Zepp to work across the whole band with stability is a bit finicky even on the design frequency. It is a lot less stable than feeding a doublet or loop.

Thanks Ace,

I saved the article link in a folder I just made on feedline info.
I will probably still have to use the tuner because there is no
practical way I can center feet a wire from where the house is placed
on the lot in relation to the trees. A large Magnolia is just
outside and across the drive from the shack which makes end feeding
the only real option.

It is a great article and I will read it again and mull over doing
the same thing to a partial degree with the end fed wire.

Thanks again ACE and 73

Hi Larry and thanks for your input.

When I meant loops I did not mean that I was wanting to coil it up
tight.
I was thinking large open gradual turns keeping the ends at least a
foot apart.

Thanks Again

Good input Jim

One thing I like about the MFJ974HB tuner is that the 50 ohm input
has a ferrite bead balun before the TX capacitors. I will keep
playing. Right now 75 and 40 work great as far as being heard.
Great signal reports. Just want to try and increase input capacity
and lower the inductance from where the tuner tunes now.

Have a great day
73's
Clint ag0k

You know what a dipole looks like.. and you know what feedline is suppost
to do...
If you take a balanced feedline and .. 'coil it up'... you distort the
purpose of balanced feedline... It should be run in a straight line, more
of less, to take advantage of it's reasons for existing...
If you want to coil up a feedline then switch to coax.. with coax you can
do just about anything... that is why they created coax....

Hi Larry and thanks for your input.

When I meant loops I did not mean that I was wanting to coil it up
tight.
I was thinking large open gradual turns keeping the ends at least a
foot apart.

Thanks Again

With respect, I disagree. Unless you dropped a couple zero's from
that, I don't think that is that far of an impedance difference
myself. Quite easily matched in fact. For a multi-band antenna I'd be
very happy with that small impedance range and not at all afraid of
keeping the transmatch in my shack.

Of course if one has a philosophical difference that precludes using a
transmatch --which is designed to match differences in impedance-- and
are willing to only use voltage baluns or tuning stubs, then it isn't
quite as simple.

But it is still far from 'impossible'! It will just require a series
of matching stubs that must be switched out at various times. (I'd
rather use a transmatch myself, but that is just me.)

I am using seven strand power line, typical power lines used for home service, I am sinking telephone poles, 50 footers and 35s on high points around the house here so as to span the coulee. The power poles are placed so there will be a minimum of ground effect. I am also using a couple of trees, one that is on a cliff above the house. that will provide about 80 feet of height right off to another tree providing about 60 feet. I have no shortage of power poles or space, I live on a 25,000 acre ranch.(Thousand, not hundred) I am feeding it with a short stretch of RG-8 out of the shack in the basement to a balun and then ladder line 450 Ohm to the antenna. I am running a single 3-500Z for output.

From: Kyle
Topic: 2326 Message: 2365

The balun I used is a Unadilla W2AU. Here is where I purchased mine, although I'm sure it available elsewhere:
http://www.universal-radio.com/catalog/antsup/1888.html

The earth goes up and down beneath the loop. Most of it is between 30-50 feet in the air in an equalateral triangle. Most of one leg is across a 1/4 acre pond, that may or may not improve performance.

My grounding plan is not really special. I am planning to put a ground rod in the earth below the feedpoint. The ground wire will run from there up to the ammo box I will store the tuner in. That will provide the common ground for the coax shields at the tuner and feedpoint, and for the static dissipating carbon resistor. Nothing really special. Right now, I don't have the ammo box up, and I disconnect the loop from the tuner whenever I'm not using it (YUCK!).

Hi Greg,

Since you will be using the loop on one band the best solution is to use coax as the feed line. You will be dealing with moderate SWR with reasonable power losses. Your LDG antenna tuner will look after keeping your radio happy. You can either connect the coax directly to the loop or use a balun of some sort at the antenna feed point. The purpose of the balun is to limit the antenna currents that flow on the outside of the coax shield .... you can use a 1:1 balun wound on a ferrite core (any number of commercial models available) or simply provide a balun in the form of a current choke on the coax (eg ferrite beads or simply wind 20 ft of coax into a tight coil).

Sometime it is an advantage to leave the choke/balun out of the arrangement and allow antenna currents to flow on the outside of the coax feed line which may give you some radiation advantage with some vertical polarization. In either case your tuner will have no problem giving you a 1:1 match.

Use 450 ladder line feed and you will be able
to use it for all bands. If your tuner only has coax
feed then use a 4:1 balun at the end of the ladder
line and coax to your tuner.

Healthfully yours,
Don W4BWS

Greg,

If you are doing this all with Coax then you will have a tough time in my opinion. The lowest frequency you will be able to get to with coax is the 20 meter band but using a tuner with ladder line up to the loop would get you lower down ☐ in fact with an SG230, you could tune all the way down to 160 meters. By all means go from the rig to the tuner with coax.

However, if you only wanted the 20 meter band (and upwards), you☐ll find that a sky loop will resonate and give you a close match to 50 ohms with a 4:1 balun (or nearly) on every harmonic of the lowest frequency. I have a 40 meter loop in the sky and it resonates on every harmonic: 7, 14, 21 and 28 Mhz. If you started life only with a 20 meter loop, you☐ll only naturally get 14 then 28 Mhz so as I started this paragraph, I was hopeful but then realised it would be a 2 band antenna. Better if you can squeeze in 40 meters of wire.

Dispensing with 50 ohms though ☐ it will work adequately if you feed it with something other than coax from the tuner

Hint, build a 20 meter loop *and* a 15 meter loop ☐ then feed them in a nested configuration with a balun (I normally find a 4:1 balun gets me close to where I want to be with a loop) ☐ you☐ll get probably everything from 20 meters upwards inc the Warc bands with a decent SWR.

(Sorry for the waffle!)

Hi Greg
Depending on where you plan to run your coax, you could run the entire length of coax with the same wire as your antenna...
This will give you a long wire antenna...
This is a very simple antenna which did work for me, and my 'series tuned circuit antenna' coupler...

Hi Greg,

The system you describe will probably work in that your tuner will adjust the impedance it sees at the end of the 75' of coax to match the 50 ohms resistive impedance your transceiver likes to see. The key part of your question is 'efficiently', that is minimal loss in the feed line and maximum power transferred to the loop. The arrangement you describe will be most efficient at 80M .... assuming the loop is a wavelength at 80m.

When operating 80M the only additional consideration might be placing a current choke on the coax at the point it connects to the loop. The reason is that the loop is a 'balanced' antenna and the coax feed line is 'unbalanced' thus there will be antenna currents flowing on the outside of the coax shield as well as in the loop. A simple RF choke will do the job, eg ferrite beads strung on the coax at the feed point or simply coil 20' feet of coax into a tight coil, also at the feed point.

However, if you operate on other bands, all bets are off .... the impedance at the loop feed point could be anything from 150 ohms to 1000 ohms or greater. Your tuner may be able to keep your transceiver happy but the high SWR on the coax will first render the choke irrelevant and power losses will become considerable ... eg transmission power will be consumed as heat in the coax. Probably won't hurt anything (if you operate 100W or less) but you will be wasting a lot of communications power.

As soon as you operate the loop on bands other than 80m then feeding directly with coax becomes dramatically inefficient. There are basically 2 solutions to the efficient multi band operation problem .... either feed the loop with open wire line to a tuner at the shack or place an automatic antenna tuner at the loop feed point and then coax to the shack.

Sorry, nothing is simple hi hi

Jim, VE3CI

Jim,

He said 70 feet in his original post (he used the ' sign for feet, like 70')

If he can actually go the distance to 80 meters then it's gonna work on all bands quite well, even with coax (I have one in my stable :) - hence the resonance on every harmonic.

Hi Greg,

The system you describe will probably work in that your tuner will adjust the impedance it sees at the end of the 75' of coax to match the 50 ohms resistive impedance your transceiver likes to see. The key part of your question is 'efficiently', that is minimal loss in the feed line and maximum power transferred to the loop. The arrangement you describe will be most efficient at 80M .... assuming the loop is a wavelength at 80m.

When operating 80M the only additional consideration might be placing a current choke on the coax at the point it connects to the loop. The reason is that the loop is a 'balanced' antenna and the coax feed line is 'unbalanced' thus there will be antenna currents flowing on the outside of the coax shield as well as in the loop. A simple RF choke will do the job, eg ferrite beads strung on the coax at the feed point or simply coil 20' feet of coax into a tight coil, also at the feed point.

However, if you operate on other bands, all bets are off .... the impedance at the loop feed point could be anything from 150 ohms to 1000 ohms or greater. Your tuner may be able to keep your transceiver happy but the high SWR on the coax will first render the choke irrelevant and power losses will become considerable ... eg transmission power will be consumed as heat in the coax. Probably won't hurt anything (if you operate 100W or less) but you will be wasting a lot of communications power.

As soon as you operate the loop on bands other than 80m then feeding directly with coax becomes dramatically inefficient. There are basically 2 solutions to the efficient multi band operation problem .... either feed the loop with open wire line to a tuner at the shack or place an automatic antenna tuner at the loop feed point and then coax to the shack.

Sorry, nothing is simple hi hi

Jim, VE3CI

>all bands quite well, even with coax (I have one in my stable :) ☐ hence
>the resonance on every harmonic
>
>

I agreed that it was possible to feed an 80M, 1 wavelength loop, on all bands 80m-10m. using coax. I pointed out that there will be high SWR's on other bands whether they are harmonically related or not which will compromise efficiency. That is a fact. The SWR the tuner sees will be related to the missmatch at the feed point and the length of the coax. Regardless what the tuner sees there will be SWR at various points in the coax and this results in inefficiency ... eg power loss.

That does not mean the antenna won't work! Heh you can work the world with 2 watts .... so if you feed 100 watts into the system at a particular frequency with 10db loss due to SWR you will still radiate 10 watts which is still more than 6db (1 S unit) more than the 2 watt QRP station working into an efficient antenna system.

So if you are feeding a 1 wavelength loop all bands 80-10m with coax then your system efficiency varies considerably. Anecdotal evidence of contacts does not change this fact or make the system efficient.

Re-reading his post, I see that he doesn□t actually specify the length of his loop which is critical if feeding with coax.

Greg, how long a loop were you thinking of feeding?

Based on 1005/3.5mhz/4= roughly 72' per side. I have plenty of land with all the trees I could need around the perimeter. Heck I have the room for a 160m loop but my Yaesu ft-101 isn't equipped with the crystal for that and I don't feel a need at this time.

I have read a few articles on the skywire loop and it seems a decent cheap antenna. I appreciate the dialog on this group and any advice will be thoroughly considered. Thanks Greg

Heck, Greg! If I were blessed with all those trees and all that
room, I think I would go ahead and at least make it a full wavelength
long for 160. You'll want it someday and it would give you some more
gain on 75/80.

Good luck with the skywire!

This brings up more questions.

How would a 160m full loop give more gain on 75/80m?

Would it matter that I do have a height limit? I can gain all the horizontal room I need but the trees only grow so high.

Would the 160 loop give even more gain on 60,40,20m?

If I just need to research this more elsewhere I will if the answers are too expansive for a reply here. Thanks for the info so far. Greg

Greg:

If you intend to use your loop on more than one band, you will most likely want to feed it with open wire/ladder line/window line and use a tuner. If so, a 160-meter one-wavelength-long loop used on 80 meters will have about 5.5 db gain at certain angles of radiation. That goes to about 10 db for 40 meters.

I'd suggest the article on horizontal loops at W4RNL's web site as a starting place: http://www.cebik.com/fdim/atl1.html.

But don't let us deter you. Put up a good loop and you'll never go back!

if it's a one wave length skywire, 50 ohm coax will work. If you have to make a real long run to the skywire then use ladder line to prevent pwr loss.

From: Paul
Topic: 2391 Message: 2391

My 40 meter full wave will have sligtly longer lines (from square) running E/W. I can feed it at the mast on a corner or I an feed it mid point on the 35 ft+ E/W leg. Would there be a difference in radiation pattern? I plan to use this n 40M and up. I'll see what the SWR is on 80. I plan to run 450 ladder line to a 4:1 balun and then to about 10 feet of coax to the shack.
Thank you,
Paul

Hi Greg,

It is simply a matter of efficiency. If you check out Cebik on large loop antennas his analyses indicate that the feed point impedance of a 1 wave length loop on 80m will represent various impedance Combinations from band to band that range from 100 to 2000 ohms .... depending on frequency and height etc. .... Average coax like RG8 ... will represent significantly larger power loss than ladder line when operating with high SWR. In a particular instance for example if you have a 16:1 SWR on 10M you could have 30watts output with 100 watts input with coax and 60 watts output with ladder line (with a 75' run). That is with top quality coax. If you were to use RG58 the ratio would be much worse.

So, yes it would probably be easier feeding a multi-band wire antenna with coax .... but it would not be efficient. Most operators are interested in squeezing out the most from their transmitters/antennas.

2393. High SWR 80/20 2WL 160

Yahoo group: SkyWires
Date: 2007-06-05 15:56:32 UTC
From: donkunst
Topic: 2393 Message: 2393

Newbie question.

I put up a 2WL 160 loop using .35 welding wire, about 1150 feet, in an elongated triangle at an average of 30 feet in height with some high points of 60 feet, on a pulley system. It is side fed with 75 feet of 300 ohm TV twin lead, direct to a MFJ tuner.

When I compared it to my HyGain vertical, 15,20,40, it didn't seem to hear as well on 2o as the vertical. Maybe it is just directional.

So here are some numbers from a MFJ analyzer.

Any ideas why the SWR is high on 80 and 20 and what I could do about it?

I got sort of carried away with the numbers, but is it reasonable that this would work all the way up to 2M? If that is the case wouldn't the gain be huge?

I like your analysis. This is very much how I log data. This business about huge gain when building bigger than 1 wavelength loops though is bunkum in my humble opinion. Dedicated loops for each frequency will give you optimum gain - for instance a single wavelength loop, vertically polarised actually represents two phased quarter-wave verticals. This sort of gain could not be achieved with a double wavelength loop. There was a contest station in the UK that built a vertical loop for 160m and thought they'd wipe the floor in a "single antenna" contest. Apparently their result was abysmal. Sorry to douse your enthusiasm.

Loops do work on 2 meters though - I have a pair stacked one wavelength apart and they do good for omni-directional horizontal work. A small yagi beats them by miles though :)

Hi Don,

You did indeed do a lot of work measuring and recording the numbers on the analyzer. You mentioned connecting 75 ft of 300 ohm twin lead to the loop (2 wl at 160m). You did not mention how you connected the analyzer to the feed line. No matter how you connected the analyzer the numbers do not mean a whole lot .... sorry, I don't mean to be facetious or rude. Measuring the impedance of an antenna such as the loop with the feed point 30 to 60 ft in the air is very complicated.

If you were interested in obtaining the feed point impedance of the antenna at a particular frequency the only way of doing that would be to attach the antenna analyzer directly to the antenna feed point ... not very practical. In this case the impedance may be measured by feeding it with a 1/2 wave length of coax feed line at the particular frequency of interest (taking into consideration the velocity factor of the coax). A reading can then be taken with the analyzer. If the reading obtained is 35 ohms +j50 for example then all that will tell you is that you need to adjust your transmitter output (modern transmitters are not adjustable) or a tuner to present an output at 35 ohms +j50. The SWR and power loss in the coax cable can then be calculated.

Wheww ... a lot of work!! And the measurement can only be taken at the particular frequency for which the coax is cut. The practical way to

approach the problem is to bring the balanced feed line to its termination point ... eg the balun in your tuner .... attach the analyzer to the other side of the tuner and start testing the frequencies of interest to see if the tuner will bring it's output impedance to 50 ohms resistive. If there are frequencies of interest that cannot be adjusted to 50 ohms then these need to be earmarked for problem solving.

Now the reason the coax feed line needed to be cut to a resonant 1/2 wavelength is that the impedance reading will be different for every other length !!! That is if the feed point is other than 50 ohm resistive !!

After you have checked the 'tuneability' of the antena/feedline/tuner system to frequencies of interest and you have created a list (hopefully a short list) ... then the easiest way of solving the problem is to add or subtract some feed line ... in your case the 300 ohm twin lead. This works since the impedance at the end will change with length. The second method is to adjust the length of the loop itself ... a lot more difficult to do.

The particular problem with 80/20 m ... is only a problem if you can't tune it to a resistive 50 ohms ... I don't know. If you can't ... even with different feed line lengths then you may be looking at loop size. There may be others with some recommendations on this count.

2396. Re: High SWR 80/20 2WL 160

Yahoo group: SkyWires
Date: 2007-06-05 19:21:38 UTC
From: donkunst
Topic: 2393 Message: 2396

Thanks for the feed back.

I connected the analyzer directly to the MFJ, a lead to a bananna plug
to the center of the coax input and the other lead to the stud.

Would you have connected it differently?

I understand that the numbers may not be accurate, but does that apply
to the SWR numbers also?

I am still trying to understand the rlationship between the
tuner/transmatch, radio and SWR. If the tuner is adjusting the antenna
to match the 50 Ohm of the radio, and the SWR on the antenna is high to
begin with, then this means although the SWR is made low by the tuner,
that very process lowers the amount of delievered power/RF to the
antenna or the efficency of the antnna. Am I thinking correctly?

What effect if any would shortening/leangthing the twin lead have?

Any comments on potential gain on the higher bands?

High SWR and Coax don□t mix very well. I hope someone else picks this up because I□m a bit busy for a couple of days but basically, aim for a good match (50 ohms) where the coax meets the balun (or another matching unit).

That's why many people feed loops with 4:1 baluns because in the mainl, you won't be far wrong. You won't be dead accurate either but the SWR will not normally be too far out.

On the other hand, some people are very keen to use twin feed (300 - 600 ohm feeder) which also works very well - but with 50 ohms required at the back of the rig, somewhere you need to transform your antenna impedance to 50 ohms to squirt the coax at it.

Need to go - good luck.

The antenna analyzer is usually designed to be similar to a transmitter with 50 ohm unbalanced output. It should be connected to the input to the balun .... if the tuner is still connected, then the components in the tuner will become part of the whole smear you are analalyzing.

>I understand that the numbers may not be accurate, but does that apply
>to the SWR numbers also?

Yes, ... if you take a particular antenna, fed by a particular feed line, at a particular frequency and you analyze the impedance/SWR at the end of the feed line, you will find that the impedance and SWR readings will change as you either change frequencies and or feed line length, and or the antenna itself. The only time this is not true is when you design the antenna to be the same impedance as the feed line. For example, if the antenna is designed to be 50 ohms (resistive) at a particular frequency ... eg capacitive reactance is balanced by an equal amount of inductive reactance .... and you couple it to 50 coax .... the match will be 1:1 and there will be no standing waves on the feed linen no matter how long it is ... it will always read 50 ohms and 1:1 SWR. With this arrangement the only loss of power will be due to the characteristics of the coax ... which the manufacturer will provide .... eg in DB loss per 100 ft of coax.

As soon as you have a mismatch at the feed point .... for example say the antenna represents 100 ohms and the feed line 50 ohms then there will be a 2:1 SWR as a result of the mismatch. The loss will be much greater as the SWR loss is combined with the normal resistive loss of the coax. You will read 2:1 at the feed point ... but you will read a different SWR depending on the length of the feed line between the antenna and the analyser. When the feed line becomes a resonant 1/2 wavelength then the SWR will read correctly again ... eg 2:1

>I am still trying to understand the rlationship between the
>tuner/transmatch, radio and SWR. If the tuner is adjusting the antenna
>to match the 50 Ohm of the radio, and the SWR on the antenna is high to
>begin with, then this means although the SWR is made low by the tuner,
>that very process lowers the amount of delievered power/RF to the
>antenna or the efficency of the antnna. Am I thinking correctly?

Okay ... here goes ... a description of the relationship .... Start with a particular antenna which you want to operate on a particular frequency. And lets say that it represents an SWR of 6:1 at the feed point. You probably won't know this. Now you connect a feed line to the antenna of sufficient length to get to the operating position ... (could be balanced line like twin lead or coax) .... at the end of the line, where it joins the transmitter you want to convert the impedance at the end of the feed line (whatever it is) to 50 ohms resistive (eg no capacitive or inductive reactance). In order to do this the common method is to use an antenna tuner ... The purpose of the tuner is to convert the impedance from whatever it is to 50 ohms. That's it.

A common way to indicate the conversion is complete is to place an SWR meter between the tuner and the transceiver. When the match is correct the SWR at the point the short coax joins the tuner will be 50 ohms ... you already know the transmitter is 50 ohms .... a match! Now for all practical purposes you have all the transmitted power fed to the feed line, and the transmitter is happy. The tuner has a range of impedances it can handle .... often published by the manufacturer. If the impedance at the end at a particular frequency falls outside that range then you may not be able to create the 50 ohms your transmitter wants. Since the impedance varies with the length of the feed line then changing the length may bring the impedance within the tuning range of the tuner.

The power that leaves the tuner will now be divided between the feed line and the antenna, and hopefully most of it will go to the antenna where it is radiated. If you are using unbalanced line feeding a balanced antenna you will often find the feed line also radiates ... eg is also part of the antenna ... another story. If there is high swr between the feed line and antenna then the amount of loss will depend on the kind of feed line you use ... eg how efficient it is in dealing with high swr conditions (generally balanced line like twin lead and ladder line is better ... more efficient dealing with high SWR).

When treating a wire antenna as a mult-band antenna the rule is to accept that on some bands/frequencies there will be a high SWR and the best feed line to deal with high SWR ... eg has the least amount of loss due to high SWR .... is balanced line like twin lead, ladder line, open wire feed line.

>What effect if any would shortening/leangthing the twin lead have?

See above hi hi

>Any comments on potential gain on the higher bands?

A loop does not have gain in the normal sense of the word .... a horizontal loop displays different radiation characteristics with size and height which will increase effectiveness for certain purposes. Eg angle of radiation ... eg the lower it is the more effective the antenna over longer distances etc .... Gain can also be expressed in terms of efficiency over other kinds of antennas ... eg a resonant dipole or a 1/4 wave vertical ...

If you google a man called Cebic ... he has written a great article that describes the behavior of horizontal loops in relation to size and height.

Larry ,
You would form a loop from a 1 wavelength length of
wire then connect the center of the coax to one end and the coax shield to the other end.

Coax to a one wavelength length of wire will be fine for resonant frequencies. So if you are going to only use the wire which is resonant on, say 80 meters, for 80 meters, you should be fine. If, however, you are going to use the wire on multiple bands, you need to use ladder line because the ladder line is much less lossy than the coax and so, even with high SWR, your antenna system will be much more efficient.

Remember with every 3db of loss in the system, you are halving your power output.

I would run 450 ladder line to the shack and then into a balun (I would try 1:1 first and let the tuner handle the rest. If you use a 4:1, its possible you may have a very low impedance on some band which the tuner may not like. However, it is still worth trying a 4:1 given the number of variables that will effect the antenna system.

2402. Re: High SWR 80/20 2WL 160

Yahoo group: SkyWires
Date: 2007-06-05 22:00:23 UTC
From: Don Keith
Topic: 2393 Message: 2402

I would definitely play with feedline length before doing anything else...that is if you are not able to tune the system for a good match with your tuner. Don't worry about the VSWR at all if your tuner finds a match on 80 and 20.

I just put up a 130-foot doublet (so I could get something higher in the air than my beloved skywire loop) and it was balky on several bands. Then I realized my random length of 450-ohm feedline was 60 feet...a quarter-wavelength or thereabouts for the design length of the antenna. I re-routed, adding 40 feet of line, and she tunes like a champ on all bands from 80 through 10. My tuner isn't supposed to handle 6, but I'm tempted to give it a try...and likely do damage to TV pictures over a dozen city blocks!

73 and we'll be listening for that signal on the loop!

From: larry allen
Topic: 2389 Message: 2403

Hi Ace.. Ratliff...
What impedance do you have where the coax connects.... just asking... do you need a coupler?...
Larry

Larry ,
You would form a loop from a 1 wavelength length of wire then connect the center of the coax to one end and the coax shield to the other end.

How do you figure that?...
Do you connect 50 ohm cable to the center of a one wavelength length of wire?.

2404. Re: [SkyWires] Coax to skywire

Yahoo group: SkyWires
Date: 2007-06-06 00:59:03 UTC
From: Dr.Ace Ratliff
Topic: 2389 Message: 2404

Larry,
I have a 1 wavelength 80 meter delta shaped horizontal loop coax fed antenna that uses a 75 ohm coax Q section in the feedline. It works better than any of the 1, 2, or 3 wavelength 160 meter loop antennas I have tried on the 80 meter band. But, I am a rag chewer and very seldom attempt to work DX on the 160 or 75/80 meter bands, although I have worked several countries. I cut the loop for 3.875Mhz and it is a 1:1 SWR at that freq without a tuner. It goes up to about a 2:1 SWR at 3.750 and 4 Mhz without using a tuner. I do use antenna tuners on my antennas when needed.

I now use a 1 wavelength 80 meter delta shaped horizontal loop antenna and a 160 meter band 1/4 wave inverted L "vertical" wire antenna. Two loops are more than I want to maintain.
If I could only have one antenna it would be a 1 wavelength 160 meter horizontal loop !

Just a note on received spam and "getting them back." unfortunately, the address you see in the email header - even the geeky full data view - are not necessarily where it came from - could be an innocent person...like me. Once week a year ago my email started filling up with undeliverable emails. turns out someone used my domain name in a spam mailing and every invalid email address in the list they used bounced back to me. And of course every delivered email had my return address on it. How can the spamee buy the product if they have my address? Because they are instructed to click on a link in the body of the email and that takes them to the spammer's site. Which in the case I'm describing was in China. We can make all the laws we want. But until our Congress grows a pair and tells Russia, China, etc. - those foreign locations from with 90% of the spams spews - that we will cut their internet access off, they will continue.
That's my story and I'm sticking to it.

Hi Paul,

I'm having the same problem with my organization domain... I get tons
of 'returned' mail...

An earlier comment was made to spam the spmmers but... that is slightly
outside of the law no matter what the situation.... and it wouldn't work
anyway because they never use a correct address's anyway... I've had to put
filters on any incoming mail that is marked as returned...

As for Congress growing a pair... won't happen... remember the cat & dog food
from China? Now we are being told NOT to use and toothpaste from China...
the Government says to throw it out but you don't see them ordering it off
the shelves... Oh yeah! don't forget the lead in the toys from China...

It wasn't too long ago that I couldn't get English candy from our friends in
Britain I haven't checked lately but if China can send us poison food and
such I should be able to get my 'un-clean' candy from Europe...

same old same old...

Topic: 2415 Message: 2424

Ace and the group,

This antenna looks very interesting, I had been planning on an 80 horizontal loop for field day, but seeing this has me thinking (looks like it will perform better above 80m, and be easier to deploy). My problem is I've already got the materials for the 80 regular loop, including over 100 feet of 450 ohm ladderline. So, my question is this, what would the impact be of attaching ladderline where the balun is, and moving the balun closer to the transmitter (at the other end of the feedline)? I've also got an Elecraft switchable balun that I've used in the past, but it isn't weather-proof enough to have hanging in the air. Basically, I usually just have a coax jumper between it and the tuner, and bring the ladderline right down to the operating station. As the antenna seems to be balanced, would there be a performance problem changing the feedline arrangement?

I'm not a big advocate of capital punishment, but I've always felt that it would be an appropriate punishment for spammers. I've heard of a couple of cases where a spammer has been murdered, and laughed about it. I saw no reason to even investigate the murder. I doubt the person who did it is going to do it again. I fully understand why they did it. :)

I changed my G5RV antenna into a Super loop BUT the twinlead or
Ladder line HAS to be 32 ft long. I added 56 ft to either end of the
G5RV , shortened the support span and pulled the new feed poit out
to a 4:1 balun where it is fed by 75 ohm coax. The whole antenna
looks like an equilateral triangle.
It works very well.

Hi Jim,
What are you using as the 1/4 wave matching stub ?
300 ohm TV type twin lead or 450 ohm ladder line etc. ???
The length of the ladder line or twin lead stub will vary with the velocity factor of the type of ladder line or twin lead used to construct the 1/4 wave stub.

"Ladder line / twin lead velocity factors vary by brand, type, insulation, wire size, etc. The best method is to use a grid dip oscillator or antenna analyzer to measure the resonant frequency of the 1/4 wave matching stub during construction, rather than by just using the mathematical formula to determine the length. "

I updated the page at
http://www.bloomington.in.us/~wh2t/Super%20Loop%20Antenna.htm
it now shows about 32 feet.

When Don/K8THU built the antenna he ended up using a 1/4 wave matching stub that was 33' 4" long.

From: Sam
Topic: 2431 Message: 2431

I want to use a ~265 foot horizontal 80m closed loop, on 160m
what I need/want to do is
open the far side of the loop when it is operated on 160m
and close it for 80m and above
how do I do that?

the loop is and has to be coax fed
not a situation where ladder line can be used!!!!!

TIA

What you could consider doing is to add a 1/4 wave shorted stub for 80 meters made from tv twin lead or ladder line at the point opposite the feed point. A 1/4 w stub shorted at the bottom acts as an open circuit at the top at the resonant frequency.
You would then have to deduct the total length of the two stub wires from the 160 meter overall length. So what you end up with is the full overall length including the two lengths of the stub operating on 160 and because the stub opens the far end you end up with 2 one wave lengths fed in phase on 80 which theoretically gives you 4 db gain.
The feedpoint has then got to be fed with a 4:1 balun and 75 ohm coax as the feed impedance is close to 300 ohms.
The shorted end of the stub can be attached to a cord and pulled back into the plane of the loop.
Remember the overall size of the loop has shrunk by approx 132 ft so it occupies a smaller area.
It seems to me that you wouldn't have to use velocity factor on the stub length in your calculations.

Hi Ace,
I remember you asking me about this design some years ago. I still have the e-mail somewhere. It didn't originate with me and I'm sure the original inventor gets miffed with us for not giving him credit. Perhaps he is just happy that we use his design. I don't even remember who he was. :-)
I don't calculate using velocity factor. I have found that when calculating velocity factor the length was always too short and I had to splice in some length that brought me close to the straight 1/4 wave. It is probably better to start with the full length 1/4 W and prune it back to suit.
I turned my G5RV into the super loop years ago and it still performs flawlessly. There is no comparison between the two antennas as the super loop lays down a strong signal where the G5RV can't even be heard.
Incidentally, I have a new one for you . It is based on a DDRR (Direct Discontinuity Ring Radiator) loop, is portable and is only 4 ft square on 40 M.
It performs at least equivalent to a dipole at 40 ft when it is only 2 to 3 ft above ground and vertically polarized. It may even out perform a dipole and certainly outperforms a G5RV at least at my QTH. It is direcional rotatable with a fig 8 pattern.I guess that is why it's better than a dipole. It doesn't need a groundplane at all. like the DDRR does so it is highly portable.
The only drawback is that it is a single band item but who cares when it is so small.
Send me an e-mail off line and I'll send you pictures and construction design details of it.

From: Callum M0MCX
Topic: 2431 Message: 2434

Sam, I did this for a 40 meter loop - turning into an 80 meter antenna when required. I did my band changes manually by running into the garden, lowering the loop and disconnecting the jumpers. I "removed" about 6 feet of wire from the 40 meter loop to make my 80m open loop. I did it last year also with my 80m loop to achieve 160 (with less success).

Suggest to make this switch-able, put a pair of relays in about 8 feet apart to remove a section of wire out the loop. Can't think of a more practical method I'm afraid - but you will probably need to support the relays somehow.

Regards,

Callum McCormick

2435. Extending Delta loop to skyloop

Yahoo group: SkyWires
Date: 2007-06-23 03:10:39 UTC
From: Marty Bluhm
Topic: 2435 Message: 2435

I've been reading my mail on the various loops that have been constructed via the reflector. I've been curious since I found Dave Fischer W0MHS article on Loop Skywire in Nov 1985 QST.

I currently have a semi-loop in the shape of a delta with the apex at 30ft in a tree. The left side of the triangle is 50ft, the right side is 60ft and the base is approximately 55ft for a total of approximately 165ft. It is felt a the corner of the 60ft side and the base with 450 ohm ladder line through a SGC 239 into RG8X.

I've been kicking around the idea of extending the antenna into a diamond shape which would add approximately 100 more ft to the antenna, giving a total of 210ft. Moving the feed point to the peak of the house, continuing to feed it with 450 ohm ladder line down to a 4:1 balun in the shack and a short piece (less than 3 ft) of rg8x to the antenna switch.

All the words I've read and using the length calculator from NS1U web site, unless I can get 544 ft out of 210 ft (really stretching it :), I can forget 160m which is my main objective with 80m secondary.

Any ideas on improving. One person was talking about hanging drop extensions from the horizontal loop. Umm. Interesting.

Any thoughts are more than welcome. This is in the planning stages. The present loop is working; but in true ham tradition, never never satisfied.

Thanks

From: Steve Holman
Topic: 2437 Message: 2437

Hello this is my first post but i have been lurking for a while.

I am building a 660 ft post tensioned loop around part of my back pasture, however the loop will enclose a 12X20 steel loafing shed for the horses. the shed is within 15 to 20 ft of the northern part of the loop. this is also the area of the feed point.

My question is what if any impact to the loop will the shed have on the loop pattern. I would assume that if it was centered in the loop it would have the least impact but offset to one side makes me wonder. I could move the loop and place the shed outside the enclosed area but that would make the installation harder and the feedline would double in legenth. The feed line is 450om twinlead.

Thanks for any comments or suggestions.

Topic: 2435 Message: 2439

Hi Callum,
Thanks for the reply. I've done a bit of rethinking. I can extend the south end of the diamond to the fireplace chimney (not in use) instead of the eaves of the house.. Doing this will give me a total of 254ft of wire. A half wave is 273ft.leaving me about 17ft shy. I'm considering cutting the 17ft into half and hanging the 8 1/2 ft vertically from the horitzontal wires. The north and south ends of the diamond will be approximately 30ft in the air with the two side poles 25ft in the air. My major problem is one side that goes through the tree at the north end hanging under some branches. Unfortunately, I cant get up into the air to lift the wire over the limbs. One solution would be to rent a bucket truck to put it over the branches. Rather expensive solution.

That is where the project stands at the moment. Getting all the items together and then some help.
Thanks again for the reply. I'll let you know how it turns out.

Hello this is my first post but i have been lurking for a while.

I am building a 660 ft post tensioned loop around part of my back pasture, however the loop will enclose a 12X20 steel loafing shed for the horses. the shed is within 15 to 20 ft of the northern part of the loop. this is also the area of the feed point.

My question is what if any impact to the loop will the shed have on the loop pattern. I would assume that if it was centered in the loop it would have the least impact but offset to one side makes me wonder. I could move the loop and place the shed outside the enclosed area but that would make the installation harder and the feedline would double in legenth. The feed line is 450om twinlead.

Thanks for any comments or suggestions.

Hi Callum,
Thanks for the reply. I've done a bit of rethinking. I can extend the south end of the diamond to the fireplace chimney (not in use) instead of the eaves of the house.. Doing this will give me a total of 254ft of wire. A half wave is 273ft.leaving me about 17ft shy. I'm considering cutting the 17ft into half and hanging the 8 1/2 ft vertically from the horitzontal wires. The north and south ends of the diamond will be approximately 30ft in the air with the two side poles 25ft in the air. My major problem is one side that goes through the tree at the north end hanging under some branches. Unfortunately, I cant get up into the air to lift the wire over the limbs. One solution would be to rent a bucket truck to put it over the branches. Rather expensive solution.

That is where the project stands at the moment. Getting all the items together and then some help.
Thanks again for the reply. I'll let you know how it turns out.

Marty,

My terrible trait of "just doing it" rules here, particularly with an SG
auto-tuner.

If you can get the loop to a half-wave or larger, then it'll work quite well
(assuming the auto-tuner grabs a match).

Subject: [SkyWires] Extending Delta loop to skyloop

I've been reading my mail on the various loops that have been constructed via the reflector. I've been curious since I found Dave Fischer W0MHS article on Loop Skywire in Nov 1985 QST.

I currently have a semi-loop in the shape of a delta with the apex at 30ft in a tree. The left side of the triangle is 50ft, the right side is 60ft and the base is approximately 55ft for a total of approximately 165ft. It is felt a the corner of the 60ft side and the base with 450 ohm ladder line through a SGC 239 into RG8X.

I've been kicking around the idea of extending the antenna into a diamond shape which would add approximately 100 more ft to the antenna, giving a total of 210ft. Moving the feed point to the peak of the house, continuing to feed it with 450 ohm ladder line down to a 4:1 balun in the shack and a short piece (less than 3 ft) of rg8x to the antenna switch.

All the words I've read and using the length calculator from NS1U web site, unless I can get 544 ft out of 210 ft (really stretching it :), I can forget 160m which is my main objective with 80m secondary.

Any ideas on improving. One person was talking about hanging drop extensions from the horizontal loop. Umm. Interesting.

Any thoughts are more than welcome. This is in the planning stages. The present loop is working; but in true ham tradition, never never satisfied.

Hi Callum

I have also tried to find info on the N4PC loop. As I understand , as described in CQ Dec-1990 , it´s a square
with 51 feet legs . A phasing line extends from corner to corner and is feed by a balanced transmission line attached at the center
of the phasing line.
Now.. that might not be the one described inEZNec (dont have that). There are several versions of the loop as I understand
it and the one descibed in CQ is a futher development of the original.
I have the CQ article if You´d like it I could try to scan it and upload it to the group.

By the way thats a nice home-page

N4PC described that loop in a article back in the 80's.
He followed up with a couple of modification articles.
I just took my 40 meter loop down getting ready for a
move. It was full wave at 25 feet above ground. I fed
it with coax as a one band antenna. After i move i plan
to reinstall it with ladder line and tuner. It worked well
for me as a NVIS antenna on 40 meters. I plan to use
it on 40,30,and 20 meters when i reinstall it.

2454. 10 meters... ?

Yahoo group: SkyWires
Date: 2007-07-01 14:46:45 UTC
From: Jason Buchanan
Topic: 2454 Message: 2454

hi all,

I've got a 160m full wave loop (it's 544' long) and am wondering if i'd buy anything making it 574' (which would help make it closer to resonance at 28.000MHz). I diddled around with it at 29.550MHz and it tunes ok there and also seems to tune ok at the bottom end for CW operation... "Seems" to anyway. Not enough going on 10 meters it seems to really tell.

So just wondering what everyone thought, if I should just leave it alone or lengthen it. And if I do lengthen it then 160 meters will be way off in terms of optimal length (very long).

thanks

Jason, you did not mention what kind of feedline you were using on this loop. If you are using coax, you will need to operate reasonably close to resonant points for the best results. If you are using open wire feedline or ladder line, you should be able to use the antenna on most bands with reasonable results. Length is not crucial so long as it is at least a full wavelength for the lowest frequency on which you intend to use it.

I doubt adding 30 feet would do much.

Jason if you are using a tuner like I am, it should be able to tune it for use anywhere, I am using 300 ohm TV wire from my 160 loop into my MFJ-944 tuner and then RG 58 coax to my radio (about 3 feet of the RG 58), and it can tune it so my radio doesn't complain.

thanks for the info - i'll leave it as is. I'm using ladder line. I was able to hear a few stations on 10m CW today and was able to tune it without my radio folding back so will leave it as is.

I noticed that there's a big, lush crop of poison ivy in the way so i'll have to wait a while anyway. hi

thanks

I'm using ladder line from the feedpoint to the back of a Dentron
Super Duper 3KW tuner - 2 feet from the tuner I have a porcelain DPDT
knife switch to toggle the polarity (15 meters seems to work best
with it reversed). The setup works pretty well - it's pretty handy
to be able to work all the bands with one antenna.

thanks

2460. MCX ZigZag SkyLoop

Yahoo group: SkyWires
Date: 2007-07-03 18:00:40 UTC
From: Callum M0MCX
Topic: 2460 Message: 2460

I've modelled what I can only call a "ZigZag" loop which has both vertical and horizontal components with some interesting gain patterns (and a small bandwidth unfortunately). Perhaps ideal for open wire feeder and a tuner but I aimed it originally at a 50 ohm match to drive it with coax - and I did it, so if you can tolerate a 50kHz 2:1 bandwidth and want a loop with lower angles of radiation, this may be your cup of tea.

I'll be happy to share my results in the form of an MMANA file if people want.

?

2461. RE: [SkyWires] N4PC loop

Yahoo group: SkyWires
Date: 2007-07-03 17:56:36 UTC
From: Callum M0MCX
Topic: 2443 Message: 2461

Thanks for the upload. I finally got around to downloading them tonight. I☐m a bit of a MMANA geek so I☐ll go and model my own and see what it says. More recently I☐ve been modelling a loop with a ground reflector and getting some huge gains on paper ☐ also some vertical loops fir reflectors; some driven out of phase ☐ and some passive. There☐s a huge amount of mucking about still left in these loops yet ☐ mind you I☐m fairly new to this game, I☐m sure it☐s all been done before.

I must say though that the author of this article discusses the excellent DX properties of a horizontal, low band loop - when used on the higher bands. I completely disagree. In practice (and the software appears to agree with this), I have found that the only possible DX from a low band loop is when you push a 40m loop into service on 20m ☐ and then it☐s really on very good for about 1,500 miles ☐ maybe shorter. All this on 30 feet and below. Modelling higher, say 50 feet still suggests the same.

Am I wrong? What☐s with this myth?

allum McCormick

Well John I guess it's good by to you, that is unless you can get the list owner to give us a little more leeway. This is GETTING TO BE A VERY TIRING ATTACK ON US. We have explained over and over and over again that the list owner DID NOT give us the ability to put new members on a moderated status for their first few posts, we HAVE looked and the list owner reserved that privilege for them self. I for one am a moderator on another ham related group and we DO have to approve new members and a few posts there.

If I seems a little touchy on this, it is because this isn't the first time some one has ask us why we allow this to happen, all we CAN do is to ban after the fact, if we could accept or reject 'new' members, I for one would like to have some one tell us why we should allow them into the group, before they become members, but as I said that is not an option for us.

Buh-bye now... seriously, the last email I got from this group was:

RE: [SkyWires] N4PC loop

and it certainly wasn't spam.

Perhaps you should consider updating or improving your email client,
there are lots of them out there, that are free that do a pretty good
job of protecting you from ever seeing the spam and phishing attacks.

Seriously, don't leave the group, but do think about some
'self-protection'. The internet is an increasingly hostile environment,
and everyone needs to do what they can to stay safe. Simply relying on
others to do so is really never going to be successful. Take on some of
the responsibility, no matter how effective or restrictive a group is,
you'll still have some junk slip through sometimes.

2469. 2 Turn Loop?

Yahoo group: SkyWires
Date: 2007-07-16 05:17:44 UTC
From: Michael
Topic: 2469 Message: 2469

Does any one care to give their opinion on this antenna?
(I found it in the groups "File" section)
Good, Bad? Is it worth a try?
Is there a UV stable zip cord?
OR use 300 Ohm twin lead OR?
Any one else have any other suggestions on this?

From: stocktonclinton
Topic: 2469 Message: 2470

Greetings Michael,

I have not tried a two turn full wave loop antenna.

While I am intrigued by the 2 files I like approaching
these things in a practical sense. I don't like to spend
a lot of time fixing antennas when I could be on the air.

I would suggest building two loops, One a one turn standard full
wave loop and then a two turn loop both for ten meters. That way you
can actually switch back and forth and see which one really does what
you want.

The turn loop [each turn being a full wave] means you are using the
same space as you would for a one turn loop. On 40, and espically on
80 and 160 you will have a lot of lamp cord between supports. I
would venture to say it will require some repair time.

My choice would be to get some copper weld wire from the wire man or
another suppliers and some 300 ohm line, and use a good tuner.

If you do build a two turn loop I would love to see your results, and
also let us know how many times a year you have to repair or replace
the lamp cord.

I hope I haven't poured out too much cold water on the idea. I don't
know of anyone personally who use one, and I was just trying to be to
practical and safe with the regular skywire loop.

My loop is a full wave 40 meter loop [144 feet] fed with 300 ohm
feed line and tuned with an MFJ 974HB tuner. I have an Off Center
Fed 137 foot wire that I use on 80 and once in a while 40. The loop
is better on 40 in most cases.

God Bless and 73's
Clint AGØK

2471. RE: [SkyWires] 2 Turn Loop?

Yahoo group: SkyWires
Date: 2007-07-16 22:54:05 UTC
From: Callum M0MCX
Topic: 2469 Message: 2471

I have modelled a loop like this for 40m and it doesn't have anything going for it bar 0.1 dBi extra gain depending on how you feed it and almost no extra gain for low angle DX.

I'd personally go either fully two element loop (like a quad or something) or stay single. Building a passive reflector about 5% larger than the driven element, a quarter wavelength behind the driven is worth it though gaining you 5.4dBi at 20 degrees against 0.5 dBi at 20 degrees for a single. If you build a passive, you can then feed the driven element at the bottom of the loop (like a horizontal loop) which makes the engineering more simple.

Thank you both!
That is what I had figured.
But, it never hurts to ask!

What it looks like I will end up
putting up is 228 foot of #14
insulated primary wire at about
45 - 50 feet in height.

Feed with 55 - 60 feet of 600 Ohm
open wire line and a 4:1 Balun at
the shack, then 20 feet of RG-213
to the tuner.

3 weeks left until vacation time and
the antenna goes up!

Exactly. I am in a number of Yahoo groups, and a SPAMMER gets in every so often. You delete it, move on, and anxiously wait for the next news story about a SPAMMER getting murdered. I get a lot more SPAM sent to my email accounts from sources other than Yahoo Groups. The SPAMMERS will stop at nothing to reach everyone with their messages. NOTHING

I moderate the WinDRM mailing list on googlegroups. Never had a problem with spam, porn, etc.

I built a SkyWires group on Google http://groups.google.com/group/skywires but it's only got one member: me hi - i'm not recommending everyone jump ship from Yahoo but if the porn continues to creep in there are alternatives.

thanks,
Jason

just do not understand how you get spam of any kind on any list when you use the tools provided to you. now, I don't know too much about this, having started with a lunchbox with a yellow screen and operating BBS' then fidonet then joining elists on the net (contrary to popular opinion - I NEVER heard of anyone named GORE concerning the origin of the internet.. just some company called DOD or USArmy or something like that) so, I have owned, operated, fought in the flamewars of the old BBS days and today, only own about 15 elists and one reflector (whatever that is). Point is, I am a newby at this but isfa I can tell, Yahoo may have a heck of a lot of problems but their FREE elists and herd of management tools are not part of them. Mostly, people not being willing to use these tools for fear of that GD'd PC Crap and OFFENDING someone, iow... the list owners are the cause of a list on YHG having spam.

I do not have any spam on my lists. but then, almost all of my lists are completely MODERATED so that nothing gets posted unless I or one of my two doz moderators lets it thru. ALL new members are automatically moderated and stay that way (most of my members have been moderated since they joined -- going back to 1998) The lists are kept ON TOPIC and are not extremely busy. I have approx 4,000 members on all of my lists. (not counting the 3 or 4 under a 100 members.). And, this thread is one that would never have started on my lists because there would be no reason for it. ie -- no spam. if there were, the comments would not have made it to the light of day. They would have come directly to me OFF LIST and I would have investigated, solved the problem. It really violates RFC 1855, Rules of Netiquette to be criticizing the moderator ON the list. That has happened a handful of times but those messages were caught and off list discussions determined that those members really wanted to belong to a different venue.<G>.

enuff, I say contact the moderator off list and assist him in setting the list to full moderation if necessary but certainly to put new members on moderation for at least a year. the old rule of a few messages, etc does not work. A few have tried that and then taught me to set a one yr wait.

cheers

The problem of the limitations of this group's Moderators was discussed a few years ago.

I think the problem is either that the group's Owner didn't grant full powers to the Moderators, or that the SkyWires group was somehow set up with some of the moderator controls permanently missing. You heard that right.

The Moderators are unable to stop a spammer until after-the-fact. Which they are vigilant about. But not until some spam has already gotten through. You can't stop something you don't know is coming.

Andy

ok, looking at the Members /Moderators section there are three (3) moderators
all created in 2004 and one owner

one, some or all of the three moderators need to be empowered so that he or
they can reset the membership settings to close this list to email address
mining, stop accepting attachments (primary method of introducing malware and
all sorts of virus type stuff.) and moderate messages until you know who you
can trust and who you cannot. oh, and of course, set all new members to
moderated. and that is just a start. Attachments can be sent to a mod and he
can put them into the FILE or PHOTO website section.

Hello all in the group !

I have been thinking to make 160mb loop, I have good
possibilities to make it. It will be 40x40 meters square,
but I dont know what are differencies between 80 mb and 160mb loops
concerning upper bands, the antenna should cover all HAM bands.
Feedpoint will be one of the dorners.

My question is: what is best solution to work 80 to 10m bands.
Is it as good to make 160 loop as 80 loop ???

About 160m band , I am sometimes speaking there but it is not
necessary if 80m loop works better with higher frequensies...

The height from ground will be abt 18 meters and the loop will be
almost in free space.

At the moment I am feeding 62 meter long wire but there are some
TVIs and Stereoreceiver problems. In this flat there are more than
hundred families and if someone is complaining it means there can be
tens of new complainings....

Please give Your suggestions
best regards and 73s ge rami, oh6bi

What is this anyway???

Modern email clients have their own filters and if configured correctly by the 'operator' you don't need to see any spam or whatever...

I know of only one list that doesn't get spam... that one I am a co-moderator of but you must understand that that one group has seven (7) moderators in each different part of the world... even then one can get by...

If you don't like spam use the filters in your email client... or shut off your computer and read all that junk mail you get from the U.S.P.O....

If you really want to have something to rave about... get a domain and play...

Agreed!

All the moderators need to do it track down the owner and have all their privileges set as "owners". They can then configure the group as most others have them, by request.

Vince, Your suggestion won't work old man, we all get the spam because it comes from the group.

2490. RE: [SkyWires] 160 vs 80 loop ?

Yahoo group: SkyWires
Date: 2007-07-20 20:46:49 UTC
From: Callum M0MCX
Topic: 2486 Message: 2490

Rami,

I was a loop fanatic. I still am but I use them as mono-banders for the low bands (I have a 40m and an 80m loop). 160m loop at 18 meters will be fantastic for one thing, 160 meters. Everything else is a compromise. The radiation pattern for multiple wavelength loops gets worse the more wavelengths you fit in and you'll get neither cloud-warming or DX capability.

At 1.9 Mhz, you'll get a lovely cloud-warmer with an 8.7dBi vertical gain, sloping off to -5 dBi at 20 degrees - this is fantastic for local (sub 1,000 miles) 160m

At 3.8 Mhz, you'll get a clover leaf type pattern with the main gain at about 6.0 dBi at 37 degrees (pretty good for 1,000 copies and some DX potential with a fair wind)

At 7.2 Mhz, you'll get something that's an utter waste of time; -5.0 dBi in the cloud-warming angle and -2.9dBi at 60 degrees. Best to use a 6 inch nail instead (this is AWFULL)

At 14.25 Mhz, you'll get a pair of shooting lobes at 56 degrees with a reasonable gain of 5.5 dBi (lobes too high for anything greater than 1,000 miles, use a basic vertical instead)

At 21.25 Mhz, you'll have large flower pattern with best gain of 7.5 dBi at 37 degrees (lobes not low enough for decent DX - use a vertical)

At 28.5 Mhz, you have a 7.5 dBi gain at 26 degrees (lobes not low enough, use a vertical)

You'll need a tuner - and feed it with ladder line because there's no way you'll match it with coax well enough to go through the bands.

(All in my humble opinion - and experience!)

A 160 meter loop should work all bands 160 - 10. On the design frequency, if in the horizontal plane, most of the energy will be high angle and should be good for regional contacts out to about 600 miles. A 160 meter loop operating on 80 meters will have a lower angle of takeoff and should produce good results with local and DX. As a general rule, the takeoff angle becomes lower as you increase in frequency, which should be very good for DX on 20 - 10. Some feed the loop with coax and some feed with ladder line. I have never had a problem using coax so long as the run is under 100 feet. If more than 100 feet, I would suggest using ladder line from the loop to a 4:1 remote balun just outside the shack and then a short run of quality coax to the rig.

Good luck OM. Let me know how it turns out. 73 de N5ETV

I have a 160, and use it on all the HF bands with no problems. I have even used it on 6m a couple of times. Mine is 30-50 feet in the air as the land slopes up and down around it. 80 for example gives me NVIS and DX. So does 40. 160 works great, but I don't know how far I can get yet; it seems to work the whole US from here (Georgia). 20 works to the horizon, then has the normal skip zone, works all over the US and I've worked Europe. 17, I've worked as far as the Leeward Islands (so far). 10 has been very active, and I've worked all over the US, and also check into local nets hearing all the local check ins that are either DX or < ~80 miles.

My loop has only been up a few months. I'm using 100W max, and I hook up my loop differently than most.

> the antenna should cover all HAM bands.
Well, I'm sorry, you're just not going to be able to work that 1.2GHz band with your loop 160m loop. ;)

73,
Kyle

2493. 60m or 60m horz loop

Yahoo group: SkyWires
Date: 2007-07-25 16:26:13 UTC
From: Sam Morgan
Topic: 2493 Message: 2493

I presently have a 60m loop ~188' The loop lays on the 2nd floor tar and gravel roof of my apartment building at 20'. The roof shape is such that the loop is a rectangle ~26' x ~68'. It's fed in a corner with ~25' of coax into a T tuner in the shack. I mainly use the loop for rx on all bands but have transmitted on 60m an 40m with reasonable success out to 750-1000 miles. Using 80watts and getting 59 to 59+ reports.

My question is related to trying to run the loop on 80m or 160m. As is I can't even get 100 miles away on 160m. On 80m much the same I can not be heard sufficiently to even get a signal report.

If I were to extend the loops long sides from 68' to 115'. I'm of the opinion that I would see very little improvement on 80m. Not worth the effort. What's the groups opinion?

I have also considered doing the above expansion to resonate it on 80m and adding a coax stub (I forget right now if it's a 1/4 wave or 1/2 wave?) but it would make the loop appear to be an open 1/2 wavelength loop on 160m. While being a closed loop for the rest of the hf frequencies from 80m -10m.

Again I wonder if the effort would be worth the results? The low height above ground being only 20' and it laying on the roof as well as the narrow rectangle shape, all seem to stack the deck against it as a transmitting antenna. And I'm not sure I would gain anything on receive either? Opinions?

I'm only considering this as a local friend is bugging me to get on 80m and 160m with him. I can already talk to him but no one else in the group can hear me.

Sorry subject line was wrong on the other attempt.....
leave it as a 60m loop
or expand to a 80m loop
(plus 1/2 Wavelength on 160m)

try this again
==========
I presently have a 60m loop ~188' The loop lays on the 2nd floor tar and gravel roof of my apartment building at 20'. The roof shape is such that the loop is a rectangle ~26' x ~68'. Topic: 2493 Message: 2495

On 160, 80 and probably 40, what you have is a NVIS antenna.
You are projecting straight up and the signals of 40meters and lower freqs
are bouncing off the f layer and back to earth in an inverted cone shape.
The cone will cover out to maybe a few hundred miles depending on power and
freq. That is what NVIS is for. Your roof is the "ground reflector".
The other bands are higher freqs and they penetrate the layer rather than
bounce off.

2497. Putting a gound counterpoise under this big loop??

Yahoo group: SkyWires
Date: 2007-07-27 01:18:15 UTC
From: radioman1044
Topic: 2497 Message: 2497

Hello, Just wondering if anyone here has tried this? I have read that it does work. My loop is up about 50 feet and in from each tower about 12 feet. If I would put a GROUND wire around it, it would be at about 40 feet and just a tad longer than the top loop. They say don't conect the counterpoise wire to anything....Not sure if it would be worth the work to put another one on...Any thoughts

It sure does work but it's hard to do comparative tests except by comparing it to signals received on a 2 nd antenna. It seems to lower the angle of the signal.
I did something similar when I built the DCTL loop . (See pictures under VE3DDY) It is actually a DDRR antenna with a ground loop underneath to replace the extensive ground plane. That is why I am able to change the way it is polarized in vertical or horizontal. The vertical mode has good directivity in a bi-directional pattern.

2504. Re: [SkyWires] 160 vs 80 loop ?

Yahoo group: SkyWires
Date: 2007-07-31 02:23:44 UTC
From: Steve Ward
Topic: 2486 Message: 2504

Kyle, I installed a 530 foot horizontal loop last week. I am feeding with coax since my entire run from feedpoint to tuner is about 50 foot. The feedpoint is just outside the shack and is up 30 feet. I have to add a small bit of inductance on 30 meters for the internal tuner to tune, but the rest of the bands tune easily. So far I have worked some 3's, 4's and 0's on 10 meter psk 31 but have not done much else with it yet other than some regional 80 meter phone this morning. You mentioned that you feed your loop a bit differently than most. I am interested to hear about how you feed your antenna. I have not yet figured out how many wavelengths my antenna would be on 1.2 Ghz..HIHI.

Kyle A <kyle@...> wrote:
I have a 160, and use it on all the HF bands with no problems. I have
even used it on 6m a couple of times. Mine is 30-50 feet in the air as
the land slopes up and down around it. 80 for example gives me NVIS and
DX. So does 40. 160 works great, but I don't know how far I can get
yet; it seems to work the whole US from here (Georgia). 20 works to the
horizon, then has the normal skip zone, works all over the US and I've
worked Europe. 17, I've worked as far as the Leeward Islands (so far).
10 has been very active, and I've worked all over the US, and also
check into local nets hearing all the local check ins that are either DX
or < ~80 miles.

My loop has only been up a few months. I'm using 100W max, and I hook
up my loop differently than most.

> the antenna should cover all HAM bands.
Well, I'm sorry, you're just not going to be able to work that 1.2GHz
band with your loop 160m loop. ;)

Callum, While it certainly is not a BIG GUN DX antenna, most dismiss the horizontal loop as a cloud heater only. 25 to 55 degrees is certainly not as good as 18 degrees but is still substantially "flatter" than what one would expect on the fundamental frequency. I worked Europe and Oceana on 10 meters in the 1990's from a previous QTH with a 272 foot Horizontal Loop designed for 80 meters. The previous loop was fed with coax and was up 40 feet. It was definately not as good an antenna for 10 meters as my 3 element quad at the same elevation. Very good for DX is not the same as Excellent for DX. I still think that a loop is a good choice for a "casual"operator who wants the simplicity of a single antenna for multiple bands. There are obviously better choices of antenna than a horizontal loop for those interested in dependable, as you say, day-to-day DX. Thanks for the comments for it is technical exchanges such as these that keep the cobwebs out of the brain.

Callum M0MCX <callum@...> wrote:
>>> very good for DX on 20 - 10.

Steve, I?ve not seen that either in practice of via modelling. All the RF is between 25 and 55 degrees, it doesn?t flatten out.

Anyone else actually done regular day-to-day DX on a 160m loop?

Subject: Re: [SkyWires] 160 vs 80 loop ?

A 160 meter loop should work all bands 160 - 10. On the design frequency, if in the horizontal plane, most of the energy will be high angle and should be good for regional contacts out to about 600 miles. A 160 meter loop operating on 80 meters will have a lower angle of takeoff and should produce good results with local and DX. As a general rule, the takeoff angle becomes lower as you increase in frequency, which should be very good for DX on 20 - 10. Some feed the loop with coax and some feed with ladder line. I have never had a problem using coax so long as the run is under 100 feet. If more than 100 feet, I would suggest using ladder line from the loop to a 4:1 remote balun just outside the shack and then a short run of quality coax to the rig.

Good luck OM. Let me know how it turns out. 73 de N5ETV

Yes, I completely agree Steve. I've worked ZL and VK from the UK on a 40m loop and of course, there is some RF given off at low angles but let us not be fooled into thinking that we have lots of RF given off at 10 degrees.

As you say though, for a casual operator, I don't think there's a better antenna, no.

I use the internal tuner thru the manual tuner. The manual tuner is set in the tune mode with the inductor set at a "K" setting [MFJ tuner] and both capacitors set at "0". I suspect that this may do the same thing as the MFJ auto range extender but I may be wrong. On all the other bands, I bypass the external tuner and use only the internal tuner.

2510. DX and a 75mtr Loop

Yahoo group: SkyWires
Date: 2007-08-11 13:49:13 UTC
From: lazysenior
Topic: 2510 Message: 2510

I read all the 160mtr Vs 80 mtr loop thread with interest. I put up a 255ft loop 3yrs ago. It is a 3 sided (delta) loop. The feedpoint apex is at 60 ft hanging off one of my towers. The other 2 supports are at about 35 ft. This means the antenna slopes. When I first put it up I used coax to feed it per the Skywire article in ARRL Antenna handbook. This setup did not perform well SWR was Quite high (10:1) on some bands. After several months I took it down and fed it with open wire feedline - the real stuff (600 ohm) that W7FG sells. This made it a much better antenna for all bands.

This antenna works better (usually) than my centerfed (same W7FG feedline) 130ft doublet. I only use the wire antennas for 75mtrs thru 30 mtrs.

Recently I got the DX bug (again). I have worked all the DX countries I could find on 20mtrs where I use a Tennadyne T6 beam.SO I decided to give 40mtrs and 30 mtrs a go for DX. The results have been eye opening. I had thought the Loop was good mainly for local (USA) contacts.NOT SO.

The last week I have worked Tahiti, Wallis and Fortuna Islands on 40 mtrs. Also Japan and Australia on 30 mtrs. These were all stations that were S6 or better on the loop. On my doublet some DX was not even heard at all...

Does a Loop work DX? it does at K9IUQ's location.....

Or I forgot to mention that I use the loop for local contacts too. It works great and is almost always better than the doublet.

Attachments: 1 described; binary payloads are missing from this source WARC

When I worked Civil Service for the
Coast Guard we installed several Folded
Dipoles made by B&W made with Stainless
Steel Wire.
The held up extremely well.

The only problem you will have is that
unless you can weld stainless you will
have to make your connections
mechanically which is not
bad. You can use Stainless Steel
hardware to connect your copper to the
stainless steel wire, and use conductive
grease to insure your
connection and keep moisture and
corrosion out.

You could also use Stainless Steel
crimps to attach copper to the wire.

I prefer Copper Weld to Stainless Steel
Wire. Stainless Steel wire is harder,
more bridle and a pain to work with.
The wire man has a copper/steel wire
with 30% cooper which is easy to work
with.

I hope this helps

It doesn't corrode, is strong and it is easy to solder. My other choice is copperweld, which I don't care for and I can't solder to the galvanized stuff, which is a pity as I have about 5,000' of it, so I'll use that to hold up my masts.

"it is easy to solder."

I was thinking about aluminum when I made this comment. I've soldered aluminum to brass or copper without problem, should've tried SS before asking. I'll try it in the morning and report back.

Thanks,

Kurt

As I recall, in addition to being very stiff, prone to 'flex breaking', it is pretty high resistance...

Nothing says you can not use it......used several antennas made with it and they worked fine....just that there are other materials that are easier to work with...

It does not take solder well at all.....plan on mechanical connection methods....

"I may be mistaken, but I don't think it is easy to solder."

I'f I had hair, I'd be pulling it out... I think the neighborhood learned some new words... I tried three times, couldn't figure out what was wrong, turned out I was using the wrong flux! Once I found the right stuff, the SS sweated as easy, if not easier than copper. I was using a whip from a CB antenna to test with, cut it in half, put the pieces side by side, about a 3\16" overlap and ran a bead down the middle. It's nice and strong too, folded the whip more than 180? without the joint snapping or peeling. I'll get some SS cable this week and sweat the ends and see how it goes, but don't expect problems after tonights quick test. I re-tested my other flux on aluminum, that sweated as easy as copper too. I can post pics to the group later if anyone is interested.

From: kd7jyk
Topic: 2522 Message: 2522

I added some pictures to the photos section.

Soldered aluminum.

I had trouble with the stainless cable, it is 133 strand, my soldering gun didn't like it, I used a torch, much harder to control the heat, but you can see in the photos, I tinned the stainless cable, tinned a penny, then soldered them both together. I was wondering what to use for lugs at the end of the cable, but I think that stainless long nuts, (threaded couplers) soldered to the ends of the cable will give me a good connection, plus something to bolt the feedline to!

I also added a picture of the stainless steel CB antenna whip I mended last night...

From: Bill Graham
Topic: 2523 Message: 2524

Dale,

The Tec Tec 229B is a great tuner, rated for full legal power, and includes a balun built-in. Also uses a roller inductor, which will extend the tuning range (useful for WARC bands, MARS, strange matches, emergency comms, ...etc.).

You'll do best to feed the loop with ladder line; 450 ohm will work fine. I strongly recommend either using 14 gauge copper-clad steel 'windowed' ladder line (Wireman type 554) for strength, or true 600 ohm ladder line (I've read very good reviews on the W7GF line). Be aware that if you use a 'windowed' ladder line (440/450 ohms), the impedance WILL change (somewhat) when wet. This can be a minor pain, since you'll produce a tuner setting chart for your frequencies of interest, which will only be a starting point when the line is wet. True 600 ohm ladder line does not have this annoying characteristic.

I brought the ladder line right into the shack, and directly to the back of the tuner. Beware that you need to keep the ladder line away from metal as much as possible, especially metal that is running parallel to the ladder line. The recommended distance is 2-3 times the gap of the ladder line (2-3" in the case of 1" 440/450 ohm ladder line). I made PVC standoffs to keep it away from the base of my tower. I've never had any problems with "RF in the shack".

Alternatively, you could bring the ladder line to an external balun (hopefully, right outside your shack), then run a SHORT length of coax from the external balun to your tuner (bypassing the balun inside your tuner in this configuration). The idea being that it's easier to get the coax into the shack (running around/across metal) that it is to get ladder line into the shack. It's your call, but a good external balun will run approximately $125.00.

Also, if there is any possibility of your loop antenna wire brushing against tree branches or whatever, make sure you use insulated wire for the antenna (I recommend Wireman type 531, 13-gauge Copper-Clad steel, again for strength).

Here in Florida, physical strength is critical if we hope for the antenna to survive the winds and storms.

I'm running an 276' 80M loop, built with the Wireman 531 antenna wire and the Wireman 440 ohm ladder line, all fed with a Heathkit SA-2060A tuner (very similar to your TenTec). The loop is only ~25-35' high, but is doing a great job on 40/80M in the evenings. If you really want to get out for DX, like any horizontal antenna, get the loop as high as possible. But, I'm telling you (there are many other testimonials on

the web of similar results) that even with the loop hung low, your results will be very, very good. And, don't forget that hearing is just as (actually, more than) important that sending, and the horizontal loop is a VERY quite receive antenna, especially on the low bands (40/80/160M) at night.

I'm moving my QTH next spring, and hope to put up a 160M loop at 60' (the land is no problem, but the height might be ... we'll see).

Good luck,
Bill AG4SI

Dale- I use a 229B to tune my 80M full-wave horizontal loop. It works very well. You will most likely need to add the capacitor on the rear connector when using it on 160M. I have my loop fed with commercial window-line (The 1" wide, 450 Ohm suff), and that comes into the shack where it is connected to a home-brew choke-balun type of thingy. (That is a 6" diameter chunk of plastic tubing about 18" long, with coax close-wound on it.) The coax continues off that home-brew device,and into the 229 tuner. I run approximately 700W or so at times, and can use the set-up on 10M-80M, and can get a fairly close match on 160M with it, although I usually use my 80M EDZ doublet on 160M. Sure hope this helps. Only thing I can mention is that on 2 of the 4 #229 tuners I have owned, the caps that are wired around the band switch were "smoked". I think they might be marginal under some load conditions. I replaced them with some nicer, higher power ones, and had no further trouble. The L-network is my favorite tuner, and The Ten Tec units are about the best ones out there.

2528. Re: 160 vs 80 loop ?

Yahoo group: SkyWires
Date: 2007-08-15 23:19:52 UTC
From: Murray Lycan
Topic: 2486 Message: 2528

I have just completed raising my previously sloping 283-foot
triangular loop.

Before configuration:
Sloping 3-sided loop with corners at 85 / 20 / 20 feet respectively.

After configuration:
Almost horizontal 3-sided loop with corners at 85 / 80 / 80 feet.
Since land slopes downward toward lower corners, loop is a little more
sloping in the SE direction than these numbers suggest.

Feed:
100 feet of 600-ohm ladder line from highest corner terminated at my
shack window into a 4:1 balun with 5-foot length of RG-8 coax to tuner.

Tuner:
Drake MN-2000

Transmit Power:
500 watts

One corner is suspended from my 90-foot tower, while the other two
corners are suspended from trees. Photo at qrz.com for VE7HA. Skyhooks
placed in trees via a homemade slingshot/fishing reel apparatus that
shoots amazingly accurately 3/4 ounce weights over tree tops.

There was a major improvement with the After configuration. The added
height is the secret. If you have the space, this antenna is simple
and relatively inexpensive. Its performance is excellent on 80 through
10 meters both theoretically and in practice.

Anybody who wants EZNEC plots, I can forward on request.
Angles of radiation are: 10 metres: 6 deg.; 12 metres: 7 deg.; 15
metres: 8 deg.; 17 metres: 9 deg.; 20 metres: 12 deg.; 40 metres: 24
deg. On 80 metres, as expected, the antenna provides excellent
local/regional coverage. It is not a DX antenna for 80 metres. Due to
poor conditions, I've not tested much on 10~15 metres. But on 17, 20
and 40 metres, it works very well.

Noise: Very, very quiet. Compared to a 12-foot high elevated Steppir
BigIR vertical with 14 tuned radials (2 per band) also installed in
the backyard, there is no comparison. With current conditions, I will
dismantle the Steppir since it is so noisy as to be unusable compared
with this loop. The loop may result in S0 to S2 noise while the
vertical will show S5 to S7 noise. And I live in a rural location with
no nearby industrial noise sources. The rig noise blanker can reduce
the vertical noise at times. But the loop is so much more pleasant to

use.

Signal strength: It's true, the vertical can sometimes produce similar receive signal strengths, but often the loop provides a higher S-meter reading. However, considering comments under Noise, I always choose the loop to use and lower the Steppir vertical radiator to avoid interfering with the loop.

Tuneup: Easy on all bands 80 through 10 metres using Drake tuner. Measured SWR at rig after tuning is typically 1.3 to 1.5. On 40 metres, SWR can be tuned to 1:1. So rig/amp are happy.

With the After configuration, characteristics are similar to using a beam antenna (without as much gain usually) except no rotation required. Generally, the loop is omnidirectional however it does have nulls in some directions and the "backside" radiation pattern can be several dB lower than "forward" direction. In other words, a yagi will probably crack pileups faster, but for sheer communication capability, the loop is hard to beat.

After playing with larger loops over the years (up to 625 feet in circumference), tips to follow religiously:
- Model first. Randomly choosing a large circumference invites failure.
- Only feed with wide-spaced ladder line. Don't think of using coax.
- Though I've not tried a 160-metre loop, I would choose it over an 80-metre loop if I had the space. My experience is that larger numbers of wavelengths on the loop add gain.
- Install the loop high. Use a slingshot. Much easier than climbing or throwing rocks at trees. Height lowers the angle of radiation.

I will try this loop for AM BCB dxing this winter. A large loop is the only antenna on which I've heard transpacific dx on the AM band. The loop is already performing excellently for SWLing.

If anybody wants a sked to hear this loop, let me know.

2530. Re: 160 vs 80 loop ?

Yahoo group: SkyWires
Date: 2007-08-16 07:04:53 UTC
From: Murray Lycan
Topic: 2486 Message: 2530

Hans,

Your suggested loop will have following characteristics according to
modeling program:
10m: 12 dBi gain @ 12 deg. elevation
12m: 13 dBi gain @ 15 deg. elevation
15m: 12 dBi gain @ 16 deg. elevation
17m: 12 dBi gain @ 20 deg. elevation
20m: 10 dBi gain @ 23 deg. elevation
40m: 6 dBi gain @ 39 deg. elevation
80m: 8 dBi gain @ vertical elevation

By deviating from the standard full wave circumference dimensions of
about 560 feet (160-metre loop), 283 feet (80-metre loop) or 142 feet
(40-metre loop), loading the antenna could become a problem for your
rig since the SWR may become quite high on some bands.

Glad to have a sked. Let me know when and where.

Hello Murray,

Many thanks for the characteristics; this is really very interesting and very kind of you!

I will use about 150 feet 600 Ohm open feeder line from the same wire as the horizontal DeltaLoop.

The antenne tuner will be the LL-Tuner, see more details on http://www.lltuners.nl/

And a home-made tuner which is developed for loop antennas. This is the GR-1500 Unbalanced-to-balanced Transmatch (ARRL handbook 198?).

Dale, I agree with everything that Bill gave you. I run a 530 foot loop up only 30 feet and have had good results. I currently feed with coax with the entire run being about 40 feet since the feedpoint is just outside the shack. My plans for improvement include feeding with homebrew ladder line to an external balun just outside the shack and then a 8 foot run of coax from the balun to the back of the tuner. R.L. Cebik has a good article posted about making your own ladder line that might be worth reading. Also, Radio Works out of Portsmouth, Virginia makes a Remote Balun built specifically for this purpose which covers 160-10 easily. Good luck with your installation. I will look for you on the air.

"I have added you to my friends network today!"

Really? Then why have me click on a link to get somewhere I already am?

Setting up the list for NON-automatic subscription will prevent spammers from using the auto-subscribe, send spam, unsubscribe, so you can't delete them bacause they no longer exist tactic, which as you can see works very well, moderators or not... You won't have to go in and manually delete all the spam from the archives any more either! I approve the members to my lists, only get one or two spam account requests a month, but it's easy to filter out accounts like domeliketheresnotomarrowandmydogtoo@... or monsterpenisforsalecheap@... it's not like the spammers use cryptic accounts that can be confused for something legitimate. Asking potential subscribers to add a little personal info helps too as an automated system wouldn't be able to send an on topic message... But, the important part is to CHANGE "Membership does not require approval", "Messages do not require approval" will not need to be changed since the spammers would no longer be able to get in. I see this has been a problem in the past, if the Owner or Moderator needs help with setting things up to prevent this, please contact me.

Kurt

Kurt,
You must be new to this list, us moderators do NOT have that option open
to us, we can only ban after the fact.
Dave N8PU

PS This has been hashed over many many times before...

I'll have to check one of my lists, it's certainly an option that can be done by the owner, will create a moderator account and double check.

2537. Control\Moderation of a Group.

Yahoo group: SkyWires
Date: 2007-08-22 04:38:08 UTC
From: Facility 406
Topic: 2537 Message: 2537

It is not my intent to beat this subject to death or put anyone down, but I read some of the comments in the archives and it is clear that many members, owners, co-owners and moderators aren't aware of how things are controlled or how they can be handled so easily, the following information solves all spam problems for all groups.

For starters, the owner or moderator with control must turn off the option "Membership does not require approval" on the group homepage. Once this is done, no spam can get through unless a moderator permits a spammer to join. The automated spam systems take advantage of groups having open subscription. Most automated systems subscribe, send spam, unsubscribe. If you find an account to ban, you're lucky! You can ban it, but expect another one within a few minutes to hours, to days, it's about as effective as killing mosquitoes near a marsh, one at a time... Solution? Cut off the water to the marsh. Not too effective it is fed by the Colorado River (BIG marsh), but you CAN take measures to ensure the mosquitoes can't breed.

Now, a quick test.

I subscribed my wife to one of my groups, changed her to moderator (one click) and was given these options (see below), basically absolute control. Each line is preceded by a check box. The owner has to give a moderator the option of what they can or can not control as each moderator is created.

I have now switched over to my wifes account after attempting to subscribe to my group with a fabricated address not meeting the requirements to get into my group. As a moderator, I can see the request and approve or deny, since it is obviously spam, I have chosen as a moderator to deny the request without any members knowing or seeing what has happened. Other than signing into my group as an owner to set moderator settings initially, everything was done through e-mail which makes it exceptionally easy, no knowledge of the group\webpage settings, etc. needed by the moderator.

Also, as an owner or moderator, I can list the messages to visually scan them for spam, click a box next to the them and delete them en masse, a good thing if the archives are public to attract new members and you don't want them to see a string of pornography ads that may turn them away.

I'll be more than happy to talk a moderator or owner through the steps to help keep a group spam free.

Moderator abilities below as seen from the group owners account, depending on what abilities you give a moderator, he\she will see these too:

Moderators can change delivery and posting settings for individual members. Check the additional privileges you want to give this moderator and click Make Moderator below.

Notification:

Notify this moderator when there are pending messages/memberships which require approval.

Notify this moderator when a member joins/leaves this group or new files uploaded.

Notify this moderator when there are pending messages which have been identified as possible spam.

Moderator Privileges:

Approve pending messages and photos Add, remove, and change moderator privileges

Approve pending members

Set auto-send options for files

Invite and add members

Change group settings

Remove members and reset bouncing members

Delete this group

Ban members

2538. Re: [SkyWires] Control\Moderation of a Group.

Topic: 2537 Message: 2538

I enjoy the group, but don't enjoy the spam. Dave has said many times
the owner did not give him the appropriate access to correct the problem.

What I have been wondering is where/who is the owner, and why won't he
allow us to fix this otherwise excellent forum?

the answer to this is to send a copy of the death certificate to YAHOOGROUPS gods and ask them to transfer ownership to <name> or something very nearly as much as a pain as that. we have had long discussions on the elist owners lists. the best way is to do what I have suggested and have done in the past.--- new list, everyone transfers themselves. those left over can be transferred from the defunct list to the new list.

everyone unsubscribes from the old list. after it has been unused for about 12 months, you can petition to use the name and then when granted, simply transfer the new list name to the old listname. it does work. I have had to do it once.

anyway, with the change to the new list, we can turn off the porn solicitations, etc.

I can set that up, move all the files over, re-assign the same moderators, give them more power to begin with and let everyone move to the new group. A mirror image, but without the 2,542 previous acrhived messages, that would be unrealistic and pointless to move over, but since the message archives are public, they could be viewed easily enough.

I set up a skywires group on Google Groups:

http://groups.google.com/group/skywires

Basically there's two options...

Join http://groups.google.com/group/skywires or make a new one on
yahoo...

The third option is to just deal with the porno garbage.

Kurt, I am afraid it is up to the moderators of the list.
I will say that if you did so, and the mods told us to move, I would be the
first to do so. or, right up there as soon as I knew to make the change.
in re the archives of the present list, I can download those over time and
then slowly upload them to the new list but they would show my From line.
I have on my HDD, 1295 of the archived messages now.
Maybe we could get YHG to move them all - over to the new list for us.
We could ask.

again, we need (the moderators need) to send a formal message to YHG to
transfer ownership to one or both of them AQAP. We might try that first.

The person for the moderators to contact would be
Jami Heldt
Groups Community Manager
jheldt@...

At least he/she could get some movement started on how to get this done.
For sure, when it does get changed -- MAKE _TWO(2)_ OWNERS immediately
Replace one every time he/she becomes non functional for the task.

I have a dozen or more elists all on YHG, I have one co-owner. He has NO
interest in any of my lists. But, he takes over whenever I go into the
hospital and he knows how to do what I want done if I happen to not come out
in a cognizant condition. (I have a terminal illness).

I will stay tuned.

I just emailed the list owner to see if he would allow us, sgordon1, dr_ace1, and me to see if he will give us more leeway in an effort to get a handle on the spam. If you feel you must I can't stop you, but I would suggest we give him some time to get my email and respond one way or the other.

I had forgotten (didn't remember) I had his email address, thats why I hadn't done it before.

Topic: 2537 Message: 2552

again, we need (the moderators need) to send a formal message to YHG to transfer ownership to one or both of them AQAP. We might try that first.

The person for the moderators to contact would be
Jami Heldt
Groups Community Manager
jheldt@...

At least he/she could get some movement started on how to get this done. For sure, when it does get changed -- MAKE _TWO(2)_ OWNERS immediately Replace one every time he/she becomes non functional for the task.

DAVID

I really suggest that you contact the above and see if they will do the transfer. point is, if we do create a Skywires2, and are later able to get the original list name, we will have lost the original archives and, gained some new message archives.

Instead, if we will simply send Jami a concise and clear message and request s/he help you get the ownership transferred, and you are successful, then you solve all the problems.

Give YHG a couple of weeks to try to contact the owner, stay on them with a weekly query. In your request, be sure to stress how long it has been since you have heard from the owner and what reply you get from mail sent to the last known address.

I will bet that you will get the list into your names in less than a month. I think it would be worth trying. especially since you have a PERSON with an email address to contact.

I would hold off for up to a month. if no luck then, then lets do the change if YOU ALL WANT TO DO SO !!! again, it is up to you guys.

From what I have heard they NEVER (well, almost never) transfer ownership of a Yahoogroup, even if the previous owner has died. Instead, they will be happy to delete the entire group (and all its files and archived messages) for you.

So be careful what you ask for, unless you are prepared to create a new group and populate it with everything important to save.

(Over on another group someone said there was one group Yahoo did transfer ownership on, under extremely unusual circumstances, and people were not successful to get Yahoo to do it again on other groups.)

2559. Loop noise

Yahoo group: SkyWires
Date: 2007-08-28 06:24:00 UTC
From: dxnature
Topic: 2559 Message: 2559

Hi OM's,

I have made a horizontal 40 loop with 17 meters of 450 Ohm open feeder line into an MFJ-941e tuner. As my dipoles worked fine I wanted a quiter antenna, but the loop has the same noise level. Last year I made a T2FD and am very pleased with it as a receive antenna, but I expected the loop to be even better, hmmm ... not so :-(

My aim now is to put a automatic coupler at the feed point of the loop and enter the shack with a coax feeder. My radio is a FT-817 with only 5 watt there is not mutch to choose from in antenna coupler world. Most of them need at least 5 watts to activate. Seems to me that the SGC-SG-211 is the one capable to run this setup. Who says that this is the way to go.

Are there other theories to get rid of the noise levels and keep the use of the open feeder? I chose this setup to use the loop as a wideband antenna to work different bands and its low loss of power.

Any suggestions???

I would suggest a good quality 4 to 1 current balun, which could be purchased at wireman.com and use coax and your tuner you are using now. The 4 to 1 balun works well. That is what I am doing and the noise is down from what I see on my 137' zepp and my log is full of DX.

From: Murray Lycan
Topic: 2559 Message: 2561

Ron,

I think it would be a shame to change your configuration. Your current configuration with ladder line right to your tuner seems more desireable than changing to coax, even with the antenna-mounted tuner. If you can try the new configuration without spending money or too much effort, do so just to try it. Otherwise, keep the ladder line configuration with tuner.

You don't say on which band/time you are having a "noise problem". How much noise? What kind of noise? Conditions in general now can be terrible on a given day/band and noise varies greatly from day to day on my loop. Noise on my 283-foot triangular horizontal loop at 80 feet high is much lower than my vertical, but I don't have a dipole to compare. Certainly, loops usually have less noise than other antennas.

Do you have reason to believe you may have a lot of local man-made noise such as generated from industrial sources? Or are you just in a regular residential neighbourhood with the usual sources?

Keeping the ladder line feed will allow lots of possibilities for multi-band operation. I operate very successfully from 3.5 through 30MHz with the single loop using ladder line.

Hi Clint,

Thanks for the reply!

Now I use the 450 Ohm open line balanced feeder. So you tell me to use the balun before the tuner? What if I put a 1:1 link coupling before the tuner and then continue with a coax to the shack. Would this not be more suficcient. It could keep a bit of static from the tuner. As the SCG tuner likes a high impedance to work with. The 1:1 will be a logic choice I think.

I decided to purchase a SG-239 today instead of the SG-211. I will mount the tuner and balun in a waterproof container at the base of my tower. From the feed point of the loop there will be about 3 foot open feeder running to the Tuner.

Another approach is to mount the tuner at the feedpoint of the loop and after that continue with a good grade double shielded coax to keep the noise to a minimum.

What say...

From: stocktonclinton
Topic: 2559 Message: 2563

Hi Ron,

Sorry I did not make clear what I would do and am doing. I have a 4 to 1 balun at the loop and bring coax all the way into the shack and then use my tuner to tune the coax just before the rig.

I found this make for a very workable system with lower noise.

I was using 300 twin lead from the antenna all the way into the shack and I had trouble with computers and on 20 meters when I transmitted it even caused my shredder to start running.

Since I put the balun at the loop and use unbalanced coax and tune it at the rig I have had no problems.

Good Luck and 73

I do think just running the coax from your rig out to the tuner at the base of the tower and open feeded to the loop should work just great. Let me know how it works 73's Clint

Hi ,
I agree with Clint "running the coax from your rig out to the tuner at
the base of the tower and open feed to the loop should work just
great" .
The only common time coax is a problem is when you present it with a high VSWR .
If you have a 50 ohm load on 50 ohm coax it will work great unless you have a very long run of coax.

I do think just running the coax from your rig out to the tuner at
the base of the tower and open feeded to the loop should work just
great. Let me know how it works 73's Clint

Murray,

Thanks for coming back on this item.

The setup with the ladder line was my initial configuration to keep the loop usable for the bands from 40 to 10 meters. I suspect to loose this as I put a balun or unun at the feedpoint and proceed with a coax.

Yesterday I ordered a SG-239 coupler and some Aircell 7 coax. At first I will mount the tuner at the botom of the tower connecting the antenna with abt 7 meters of ladder line. From the tuner to the shack I will use the coax and will see how thing are going. If the amount of noise is still prominent, I will put a 1:1 link coupling between the ladder line and the tuner.

The noise is not always present. It is all over the bands, even if there is no propagation even if the bands are not active, like 10 meters at night. It is evidend that the noise levels on 80 and 40 are higher. I live abt a mile out of town and the nearest industrial park is also a mile out on the other side. Not an ideal location, but there are no high tension powerlines or electric railroad in sight. I have to keep my plasma tv turned off for sure, hi hi :-)

I will keep you posted with the results.

many thanks,
Ron

Howdy Clint,

Can you still use your loop on all the bands with the 4:1 balun and
the coax?

Hi Ron,

The 144 foot loop tunes on all amateur bands from 7.0 through 29.7.

The MFJ-974HB antenna tunder has a very wide range so I can tune the loop to with no difficulty.

Now my inboard tunner on my TS-440S will only tune it on 40,20,15,and 10. The SWR is two high on the warc bands.

I just tune it with the MFJ no matter what band I chose.

I hope that helps.

73's AGØK Clint

Hi Ron ,
I have read that running the coax on top of the ground at the bottom of the tower will decouple it from the tower. That is how I have mine. But it sure won't hurt to bury it , if it (the sheath) is rated for direct burial.

From: Murray Lycan
Topic: 2559 Message: 2572

When I first moved to this location, I had terrible noise. I couldn't understand how a rural location with few nearby neighbours could be so noisy. Using the normal procedures of switching off everything I could inside my own house, I finally discovered on the floor of my radio shack an extremely electrically noisy "Made in China" inverter power cube that was powering my Internet cable modem. To find this, I had to turn off the power to my radio shack and run the radio on battery.

I threw that cube across the room and replaced with a Made in U.S.A. product. All noise problems disappeared.

2573. Open feederline through the wall

Yahoo group: SkyWires
Date: 2007-08-30 04:40:40 UTC
From: Hans Remeeus
Topic: 2573 Message: 2573

Hello,

Yesterday I installed a DeltaLoop of 410 feet length (125 meters) at 35 feet height (10 meters) between three wooden poles of about 8 inch (20 cm).

I will use open feederline of 165 feet (40 meters) from the same wire as the DeltaLoop.

What is the best solution to bring the open feederline through the wall? The outside and inside walls are made of bricks. Together the wall is less than 1 feet (30 cm) thick.

Any practical ideas?

Many thanks in advance.

When I needed to go thru a thick Masonry wall of that type I drilled 2 holes the same spacing as the feed line using a long mason bit and a dewalt hammer drill.

I then pushed .250 copper threaded rod thru those holes. Using a copper flat washer and nut on each side to pull it up tight. I soldered solder tinned closed loop terminations on the exterior ladder line. With another copper nut I made the exterior connections. Inside I pretty much did the same thing but I used an open lug and copper wing nuts so I could disconnect quickly in Electrical storms, high wind and heavy dry snow to avoid static buildup issues. A bit of Silicone or exterior RTV under the flat washers on both sides would keep any moisture and little critters outside where it and they belong.

I am sure there will be many points of view that will come out and not knowing exactly what you situation looks like I figured I would pass on what worked for many years for me.

Good luck

You could also drill two holes, same spacing as your line, insert plastic tubing or small pvc pipe. Strip back enough spacers to get the line through the wall and then connect enough line inside to get to the tuner.

If you have a 2 ft piece of rg-8 just laying around the coax idea would work great as well. I haave a friend in missouri who just used the center insulator and wire throwing away the braid and outer jacked.

Any of these should work. I am assuming that the copper all-thread, which is an idea I like had some sort of insulation around it through the holes. Wet Brick will conduct.

Have a great day
73's AGØK Clint

I soldered solder tinned closed loop terminations on the exterior ladder line. With another copper nut I made the exterior connections. Inside I pretty much did the same thing but I used an open lug and copper wing nuts so I could disconnect quickly in Electrical storms, high wind and heavy dry snow to avoid static buildup issues. A bit of Silicone or exterior RTV under the flat washers on both sides would keep any moisture and little critters outside where it and they belong.

Topic: 2573 Message: 2577

Of course, the BEST way is one continuous run of open wire, all the way to your matchbox (or balun, if you only intend to use the antenna at resonance), but that is not an option for many of us. I use the following two methods, and both seem to work well.

1) On my skywire loop, I run 450-ohm ladder line to a hole in the brick wall of the basement where the air conditioner feeds through. There, I have two parallel pieces of RG-8 (NOT 8X!) coax taped together that make a run of about 12 feet (3.6 meters) to the shack and tuner. I use banana plugs to tie each leg of the ladder line to each of the coax center conductors. The coax shields are tied together at the tuner end and attached to the station common ground and the two center conductors go right to the balanced output of the tuner. Considering the varying impedances seen using this antenna system on every band, the impedance of the parallel coax cables is no big deal. The run should be as short as possible and the coax as low-loss as you can get. When not operating, I disconnect the banana plugs outside and drop the feedline on the ground for lightning and static-buildup protection.

2) For a flat-top all-band doublet (135 feet or 40 meters long, I run the ladder line to a DX Engineering 1-to-1 balun mounted just above the hole in the brick, then have a short run of RG-213 to the tuner. Again, "short run" is the operative word on coax. And I use banana plugs on the ends of the ladder line to the balun for the same reason as above...quick disconnect when it thunders.

There's argument about the ratio of the balun for such a setup. Some say 4-to-1 or higher since the ladder line is 450 ohm, nominally. Truth is, the impedances will vary all over the place, depending on frequency and other factors. Since most tuners handle higher impedances better, I prefer passing along whatever the feedline and antenna throws at the tuner rather than risk having the balun stepping down an already low, low impedance.

Good luck with the antenna. I'll wager it will serve you well.

2578. Re: [SkyWires] Open feederline through the wall

Yahoo group: SkyWires
Date: 2007-08-30 15:40:39 UTC
From: Donald Sanders
Topic: 2573 Message: 2578

I have mine running through the wall by drilling two holes through the wall to pass a 1/8 inch threaded rod. I slipped plastic sleeving over the rod where it is in the wall. I fasten the feedline on the outside to the rods with 2 nuts and a crimp lug on the feedline wires. I do the same on the inside with a 4:1 balun on the inside and coax to the tuner. I can also run balanced line to my other tuner on the inside.
I have a friend that runs 300 ohm thru the wall inside a piece of plastic pipe and then 450 line external and internal to the station.

Healthfully yours,
Don W4BWS

Subject: [SkyWires] Open feederline through the wall

Hello,

Yesterday I installed a DeltaLoop of 410 feet length (125 meters) at 35 feet height (10 meters) between three wooden poles of about 8 inch (20 cm).

I will use open feederline of 165 feet (40 meters) from the same wire as the DeltaLoop.

What is the best solution to bring the open feederline through the wall? The outside and inside walls are made of bricks. Together the wall is less than 1 feet (30 cm) thick.

Any practical ideas?

Many thanks in advance.

2579. Re: [SkyWires] Re: Loop noise

Yahoo group: SkyWires
Date: 2007-08-30 12:33:36 UTC
From: Vince Werber
Topic: 2559 Message: 2579

Hi All,

My loop is 280 feet and my old Johnson match box handles it excellently on all bands.

As for noise... My loop has less than half the noise of my reference dipole at 35 feet...

If I were getting a comparative amount of noise on my loop as the dipole the first thing I would check would be the balance of the overall loop and feed line... more of the feed line tho... In order for the noise to be cancelled the feed line must be balanced... objects close to the feed line or the loop can cause imbalance...

Dear Don and others,

Many thanks for all the very interesting information! This helps a lot.

I use the DX Engineering 1:1 and 1:4 baluns and I am very curious how
they will work with the DeltaLoop.

Untill now I always used dipoles with the PA0LL tuner. Have a look for
this tuner at http://www.lltuners.nl/. However I also want to use a home
made tuner with 1 variable C and 4 coils.

Tomorrow I hope to finish the installation and do the first tests with
the DeltaLoop.

2581. Loop parasitic element?

Yahoo group: SkyWires
Date: 2007-08-30 22:42:39 UTC
From: Bruce Conner
Topic: 2581 Message: 2581

I was doodling in a meeting today (so sue me!), and I had an idea about a possible improvement to a full wave horizontal loop. Maybe this has been done before, or maybe my thinking is flawed; let me know. Here's what I was thinking:

You have a square horizontal loop, full wave for 80 meters - standard stuff. The takeoff angle improves as you use it on 40 and 20, but loops are still not known for their wonderful takeoff angle, even if they do work DX OK. I was hoping to improve that, at least for 20 meters. So rather than using a parasitic element to boost gain in one direction, I was thinking, what if you could use it to lower the takeoff angle? Here's how (I hope). You have the 80 meter loop as the driven element (say 70 feet on a side) and INSIDE that, at about the same height, you suspend a 20 meter loop (about 35 feet per side)with no connections, just parasitic. It is spaced at about 1/4 wavelength from the outer loop all the way around. A small loop inside a big loop.

Would this have the takeoff angle lowering effect I'm looking for? I know people have stacked loops vertically, but I've never seen one set up as a square donut before. Anybody care to comment (or point and laugh)? I haven't done much with antenna modeling software and I have no idea if any of them could handle this anyway, but if someone cares to try...

From: Adam
Topic: 2582 Message: 2582

Hello All, Has anybody tried or have any thoughts on how suitable multistrand Stainless Steel Wire would perform say compared to good copperweld?

Its hard to get good copperweld in Australia & I'm finding it difficult to obtain electrical conductivity info on SS Wire rope. I also tohught SS Multistrand wire would stayup a lot longer but I'm concerned about its conductivity (ie. lack of information).

I was originally looking at a single strand of Stainless Steel MIG/TIG welding wire of ~1.1mm for my new HOPL as the MIG copperweld I use keeps rusting out.

Has anybody sucessfully used Single Strand or Multistrand Stainless Steel Wire/Wirerope?.... I would like to hear from you.

Adam,
I have not tried the stainless wire , or have not found the electrical conductivity.
From the advertisement Bushcom uses stainless wire in making their antennas.
I have seen some others using stainless wire.
Long time use in mobile antennas

BBA-100 HF ANTENNA

Our flagship model and all round best performer to date is the BBA-100 Antenna.

Highly efficient, engineered to meet the exacting standards of professional users, yet comparatively affordable, the BBA-100 has much to offer to a wide range of private and commercial users.

The BBA-100 is adaptable enough to suit a wide range of installation situations - from between two purpose built antennas at a professional site to between a tree and the backyard shed and even in an inverted "v" configuration*.

Light, yet sturdy construction ensures low total mass wind loading even though the highest quality materials are used in construction, such as stainless steel wire and fittings and UV resistant fibreglass rods This produces an antenna that will survive the rigours of the outdoors for many years.

A range of BBA-100 variants are available - including shorter, longer and 500W (AM) & 1KW variations. These models include BBA-100S, BBA-100E, BBA-500, BBA-500E.

Give Packet Radio a try ....Mississippi.......145.010.......Simplex.......1200 Baud

Try a plexiglass insert cut very close to width dimension of your window and a height of about 6 inches into the nearest window. Slide up the window abovr the height of the insert. Put some sticky backed foam insulation around the perimeter of the plexiglass insert and close the window down on the insert. A couple of L barckets mounted between the upper and lower window will hold everything in place. Drill a couple of holes with the spacing of your open wire line and pass the wire through.

Works great for me.

Hello Adam,

I have had experience with stranded Stainless Steel wire for a
160meter loop.

It has pros and cons, The pro is of course durability/strength etc.
The nice part also is that it doesent tend to stretch much so the
frequency will not vary a lot with temperature variances.

The Cons/downside of the equation is this. Stainless steel is not as
conductive. I had heard (and I do not at this time remember the source
but it was a ham) that Stainless Steel was only .8 as conductive and
radiative as copper wire/or copper weld.

If this were indeed true, I should think you would be looking at a
minimum of a 20% signal reduction (likely more by the time you
calculate DB algorythms and such), of efficency loss.

Of course if stainless steel was all I could get my hands on to get on
the air, I would certainly use it! HI HI!

I Inturn also would take steps to build a taller, or more complex
array to compensate for losses in other areas, paying special
attention to areas where I could compensate for "CURABLE" loss.

Hope this is of some assistance, Bryan Kc8hps

p.s. as a side note though, my stainless steel loop survived a major
ice storm with no damage :) .--- In SkyWires@yahoogroups.com, "Adam"

To Adam and All
Hope some of this information will be helpful:
73 Ken

Electrical Conductivity of Metals, including some alloys

* At 20° Celsius, based on copper as 100.
** Per degree C at 20° C.
Note: The conductivity of various metals is subject to variation according to processing and alloy composition.

Aluminum 59
Brass 28
Cadmium 19
Chromium 55
Cobalt 16.3
Constantin 3.24
Copper:
Hard drawn 89.5
Annealed 100
Gold 65
Iron:
Pure 17.7
Cast 2-12
Wrought 11.4
Lead 7
Manganin 3.7
Mercury 1.66
Molybdenum 33.2
Nichrome 1.45
Nickel 12-16
Nickel silver 5.3(18%)
Phosphor bronze 36
Platinum 15
Silver 106
Steel 3-15
Tin 13
Titanium 5
Tungsten 28.9
Zinc 28.2

http://www.vk1od.net/rigging/sag.htm
The Link above will have the full article
Cut some information out and placed below:
30% Copperweld

30% Copperweld has sufficient cladding thickness that the wire's conductivity is similar to copper over most of HF.

Copperweld delivers most of the strength of medium/high tensile steel and the conductivity at HF of copper.
2.7mm XL

The 2.7mm dia "XL" wire is an electric fence wire by Gallagher. They claim it is a high tensile steel wire clad with

aluminium, 30% by csa. Gallagher have supplied mechanical properties of the wire. The cladding thickness is 223

microns, which is sufficiently greater than the skin depth on HF that the wire's conductivity is similar to aluminium. XL

delivers 70% of the strength of high tensile steel and the conductivity at HF of aluminium (about 78% of copper at HF

due resistivity and skin effect).
Stainless Steel

Stainless steel has more loss than copper, and depending on the antenna, thin stainless steel wires may add 1 to 4 dB

of loss compared to copper.

Small diameter stainless steel is used in many commercial wideband HF antennas. Many if not all of these antennas

incorporate bulk resistive loss elements (eg T2FD designs) and loss in the antenna wire just means less loss needed in

the bulk loss elements. If an antenna doesn't depend on inherent or built in loss to achieve objectives (such as

improved VSWR over a wide frequency range), don't use stainless steel without considering its loss.

Subject: [SkyWires] Re: Hello - Any thoughts of using say 3.2mm multistrand Stainless Steel Wire

Hello Adam,

I have had experience with stranded Stainless Steel wire for a
160meter loop.

It has pros and cons, The pro is of course durability/strength etc.
The nice part also is that it doesent tend to stretch much so the

frequency will not vary a lot with temperature variances.

The Cons/downside of the equation is this. Stainless steel is not as conductive. I had heard (and I do not at this time remember the source but it was a ham) that Stainless Steel was only .8 as conductive and radiative as copper wire/or copper weld.

If this were indeed true, I should think you would be looking at a minimum of a 20% signal reduction (likely more by the time you calculate DB algorythms and such), of efficency loss.

Of course if stainless steel was all I could get my hands on to get on the air, I would certainly use it! HI HI!

I Inturn also would take steps to build a taller, or more complex array to compensate for losses in other areas, paying special attention to areas where I could compensate for "CURABLE" loss.

Hope this is of some assistance, Bryan Kc8hps

p.s. as a side note though, my stainless steel loop survived a major ice storm with no damage :) .--- In SkyWires@yahoogroups.com, "Adam" <mada73@...> wrote:

2587. Re: Hello - Any thoughts of using say 3.2mm multistrand Stainless Steel Wire

Yahoo group: SkyWires
Date: 2007-09-01 19:11:11 UTC
From: stocktonclinton
Topic: 2582 Message: 2587

Here is some information I found on the pages produced by Cebik.
Looking at the list of materials for making an antenna SS would be my
last choice.

73's AG0K Clint

Test 1: #14 wire dipole for 7.0 MHz
In this test, I took a resonant dipole model using lossless wire and
then changed materials (from the usual list of materials) to see what
the effect might be. Here is data on free space gain, source
impedance, and efficiency for a number of materials. 6063-T843 and
6061-T6 are common aluminum allows used mostly in tubing that we find
in HF and VHF beam antennas. The "Ey" notation is common computereze
for "x 10 to the y power." Note where the list changes from E7 to E6.
Conductivity Material Gain Source Z Efficiency
S/m dBi R ± jX Ohms %
Perfect (lossless) 2.13 72.2 + j 0.1 100.00
6.2893E7 Silver 2.04 73.7 + j 1.4 98.09
5.8001E7 Copper 2.04 73.7 + j 1.5 98.01
3.7665E7 Pure Al. 2.02 74.1 + j 1.8 97.54
3.0769E7 6063-T832 2.01 74.3 + j 1.9 97.28
2.4938E7 6061-T6 2.00 74.6 + j 2.2 96.98
1.5625E7 Brass 1.96 75.2 + j 2.7 96.19
9.0909E6 Phosphor Bronze 1.91 76.2 + j 3.6 95.02
1.3889E6 Stnlss Stl 302 1.55 83.0 + j 8.8 87.53

Note that even silver (untarnished) shows a 2% efficiency loss and a
0.1 dB gain loss relative to perfection. Even if silver were cheap, I
would not waste it on a wire antenna of this kind, given the
performance of copper. Also note the larger step drops as you move
below pure aluminum on the list.

2588. New DeltaLoop

Yahoo group: SkyWires
Date: 2007-09-01 20:08:52 UTC
From: Hans Remeeus
Topic: 2588 Message: 2588

Yesterday I finished the installation of the 410 feet long horizontal
Delta Loop antenna at 30 feet height.
The open feeder line is about 125 feet long.

You will find a photo impression on
http://www.remeeus.eu/hamradio/antennes_tuners/deltaloop.htm
I did'nt have the time to translate the text into English, but I will do
this the coming days.

Signal reports (RX as well as TX) are dramatic good!

For the time being I did put the open feederline through a ventilation
roof tile, instead of through the wall. You will see this on one of the
photo's.

Sked are very welcome to test the DeltaLoop on 14 MHz!

Very nice work, where did you get the spacers for the ladder line,
those are real nice.

"Stainless steel has more loss than copper, and depending on the antenna, thin stainless steel wires may add 1 to 4 dB"

Any idea what "thin" is? I am considering 3\16" or 1\4" stainless for my antenna.

Kurt,

I don't think you read that correctly. Thin stainless wires may add 1 to 4db *of loss* over copper.

Thanks John.

The spacers can be seen and bought at
http://www.hfparts.com/html/spreizer.html

However this site is in the German language (yet). If you need any
translation, just send me an e-mail.

I use the SP-120 spacers for 110 mm (4.33") spacing.

These spacers have a hole in the middle, for mounting them on any surface.

Thanks Clint.

The mounts are also from Germany, just as the spacers.

However I bought the spacers at a local company who installs lightning protections.

The mounts are from zB-S Technic in Durmersheim/Germany.
They have a site in the English language:
http://www.b-s-technic.de/B-S-Technic_Release%20Englisch/start_eng.htm

The product is Duplu-Clip. I used the 4 (1.56") and 6 (2.36") cm mounts.

I am afraid you have to buy at least 100 pcs. The same problem I had.
Perhaps your local radio club is interested in buying these mounts and the spacers.

LACKING aluminum or copper or better conductors (meaning LESS LOSS), if SS is all you have, then use it. but it is really heavy. for the same strength as copper, why don't you try to find something lighter in SS? if those are all you have access to, then fine.

point is, get it up and get on the air.<G> it is too bad we are selling all of our copper to the Chinese who will send it back to us one day I expect. but until then, do you have copper access thru trading partners there in the area such as the Philipines, or so on??? These probably could obtain US copper from the Chinese at a lower cost than our copper wire which is likely made by the Chinese and shipped back here for sale.

iow, think about online purchasing from your "area" Western Pacific neighbors. I would go see what I could get from Singapore.

good luck

Hans,

Looks beautiful and professional.

I'd be happy to try a sked, but studying the path on my propagation program indicates a QSO could be a challenge with current conditions. I'm available 1600~0700Z most days. What time would you suggest? When do you hear west coast North America best on 20 metres, if at all now?

2598. Twinlead on the ground

Yahoo group: SkyWires
Date: 2007-09-03 03:50:58 UTC
From: Paul
Topic: 2598 Message: 2598

At home I can route Twinlead so it stays "in the air" until meets the balun to switch to coax. But in the field, I'm not so sure how high the antenna will be. I could just just the TwinLead feed to around 15 feet and put a 4:1 balun there and switch to coax. Or I could put the 4:1 right at the supported connection point of the wires in the air and run coax all the way to the rig. Or, I could run Twinlead all the way to the operating table and convert via the balun there. But if I do that, the twinlead will probably lay along the ground - depending upon terrain.

Is it best/imperative to keep the twinlead off the gound?
Thank you and 73,
Paul

From: dxnature
Topic: 2559 Message: 2599

Ace,

Yes I run the ladder line trough a wooden window about straight in to the tuner. Distance window / tuner is about 3 inch. From there I use 6 foot of coax into the tranceiver.

As of yesterday the loop is running via 52 feet of 450 ladderline into a SG-239 coupler and 6 foot coax into a QRP tranceiver. The loop is still at the same position and is producing noticably less noise. In fact the only major difference is the SG-239 coupler???

I'm a happy camper at the moment!

Many thanks to you all for the tips.

2600. Re: [SkyWires] Open feederline through the wall

Yahoo group: SkyWires
Date: 2007-09-07 14:57:28 UTC
From: Jason Buchanan
Topic: 2573 Message: 2600

I bored a 15/16" hole through the wall to the outside of the house and ran the ladder line through the hole (i'm using #16 gauge black PVC coated window line). The hole is behind the plastic window shutters (hides the hole when it is time to move out of the house). The ladder line runs up the side of the house and runs along the underside of the eaves. I use ceramic fence post insulators to hang the ladder line under the eaves. I placed the insulators at intervals that met the holes in the ladder line. At the side of the house I use banana plugs to disconnect the feedline. I painted the insulators and feed line with leftover latex paint and it's nearly invisible.

I may get a hole saw and put a piece of 2" PVC pipe through the wall but it works fine as is. I used silicone sealant to plug the hole on the outside of the house, to keep the little beasties out.

I have always used stand offs on my ladder line at my tower and any metal that it came close to, but in tha house I run it along the floor joist in the basement. Do you think that can cause a problem? I never thought much about it being close to wood.

Subject: Re: [SkyWires] Open feederline through the wall

I bored a 15/16" hole through the wall to the outside of the house and ran the ladder line through the hole (i'm using #16 gauge black PVC coated window line). The hole is behind the plastic window shutters (hides the hole when it is time to move out of the house). The ladder line runs up the side of the house and runs along the underside of the eaves. I use ceramic fence post insulators to hang the ladder line under the eaves. I placed the insulators at intervals that met the holes in the ladder line. At the side of the house I use banana plugs to disconnect the feedline. I painted the insulators and feed line with leftover latex paint and it's nearly invisible.

I may get a hole saw and put a piece of 2" PVC pipe through the wall but it works fine as is. I used silicone sealant to plug the hole on the outside of the house, to keep the little beasties out.

Hello Keith,

My experience is that this does'nt matter.

However I use the same standoffs at the wall inside the shack as I use outside. But this is more for a good look.

The only problem I have experienced with open feederline is snow...

Hello Paul,

You always have to keep the twinlead (or any other open feederline) off the ground, when it is outside the house.

Inside the house it is not a problem to lay it along the ground. As far as it will not get wet.

Putting the 4:1 right at the connection point and run coax to the shack perhaps is the most easiest way.
I did it the more difficult way, hi! Just have a look at http://www.remeeus.eu/hamradio/antennes_tuners/deltaloop.htm
I use 4:1 balun inside the shack as well as a balanced tuner. This gives me some more flexibility.

Thanks Paul and Chris.

It was very nice to do. It took a lot of thinking and reading, in this group too!

I hope other people will get ideas about how to make a loop antenna and how to lead an open feederline to the shack.

This is very interesting, I don't recall reading much about this. I always wondered how to turn corners and I'm still not quite sure?

Is there supposed to be exactly the same amount of line in each side of the feeder..?

Hello Callum,

A minor difference of (lets say) a few inches compared to the
feederlength of 150 feet would not harm very much. I my case there are
left corners and right corners, so afterall the difference of length of
the open feederling could be ignored.

Enjoy your new linear amplifier! I use the same one, for a couple of
years. Great amp.

...Or It Explodes!!!
...Always!

Strangely, in light of this newly discovered physical law, one past year during field day I strung up a low 135-foot long dipole (that's the total length), connected it with something like 60-feet of window line, and dropped that on the ground for over 20-feet. I did however manage _not_ to loop it around the metal awning of the pavilion.

No flames. Not even smoke. Worked my state of Missouri just fine. Good signals in both directions.

Not that I am recommending this as good design. But to say open line must _always_ be kept off the earth is simply _not_ true.

(That, by the way, is usually the proper reply when someone says something _always_ is true, and doubly so in the world of amateur radio.... always!)

> Inside the house it is not a problem to lay it along the ground. As far
> as it will not get wet.

Rain, nearby metal objects, magnetic fields, positive ion concentrators (e.g. concrete).... I think you'll be better off reading on your own about open feed line and what conditions it is designed to work properly with, what conditions cause dramatic difficulties, and use your best informed judgment when bridging situations somewhere between these extremes. But it isn't as simple as merely keeping it dry.

>> At home I can route Twinlead so it stays "in the air" until meets the
>> balun to switch to coax. But in the field, I'm not so sure how high
>> the antenna will be. I could just just the TwinLead feed to around 15
>> feet and put a 4:1 balun there and switch to coax. Or I could put the
>> 4:1 right at the supported connection point of the wires in the air
>> and run coax all the way to the rig. Or, I could run Twinlead all the
>> way to the operating table and convert via the balun there.

Loss is the only thing that is important. And if you are talking about HF, it isn't all that important, and especially not across short runs. But I digress....

Experiment. All of the above may work. There are many variables, some of which are unique to each site. In general, balanced line (of any design, be it, open, twin lead, ladder line, or window line) has much less loss

than coax. This in turn often provides much more flexibility when using it. I find this especially useful in portable operations. At home you can fiddle and tweak to your heart's desire and maximizing system flexibility is not quite as important.

Whatever you decide, or experiment with, be aware that if you also have available several different lengths of coax you can quickly and simply alter the complex impedance your antenna system delivers to your XCVR (or transmatch). Should you find you cannot tune a given set-up just add (or subtract) about 10% of a wavelength (or any convenient random length of coax you already have on hand) and try again. Changing the length of coax will in nearly all cases alter the impedance "seen by" your XCVR (or transmatch). If that new impedance is within the tuning range of your XCVR/transmatch, then you are in business, making contacts! If not, try a different length of coax.

If you alter the length of coax by 25% or 50% of a wavelength at the frequency giving you trouble you will have done a lot to easily alter the complex impedance to a value that may be usable. If this fails a more complex solution may be required. But altering the length of coax is a simple and easy means to try first, and is very easy to implement in the field.

If you find you cannot tune your antenna system, you might, just for fun, try stomping your twinlead into the ground! This will alter the twinlead's dielectric value, altering its impedance, which in turn will alter the complex impedance ultimately delivered to your XCVR/transmatch. (It will tend to be more lossy too -- but you may make a contact whereas before you couldn't even tune the system!)

Or it still may not work at all. Try it and see what happens!

>> But if I
>> do that, the twinlead will probably lay along the ground - depending
>> upon terrain.

When operating potable my friend and I have successfully raised our ladder line above the earth by taping it to fiberglass with electrical tape. We found some reflective markers, as one might use to mark the edge of a driveway, and discovered the shaft was fiberglass. And reflective! We found this useful at night. It keeps the "extra" ladder line above the earth and is easy to see when stumbling about at night holding only a flashlight for lighting your path.

(But using metal anywhere near balanced line is not a good idea, so don't use metal poles to support your twinlead above the earth. "Anywhere near" means no closer than the width of the balanced line. And further away is even better.)

>> Is it best/imperative to keep the twinlead off the gound?

You should generally find the twin lead operates better when _off_ the ground, but it will "work" either way. I've even had had one corner of a loop fall onto the earth and still "work" -- it was acting very strangely and required frequent retuning, and was basically a pain in the rear-end to use, but it did in fact allow me to transmit and receive RF signals. So while it worked it did not really work very well, and it clearly did not work anywhere near its maximum efficiency. Be aware each of those is measured by different standards.

In short --if that remains possible-- read and ask questions, then do the best job you can with what is at hand, and so long as the impedance delivered from the antenna system to your XCVR (or transmatch) is within that devices ability to load into safely, you will make some contacts, and the system will "work". This is not to say you won't be able to improve upon it.

This is part of the fun of antenna systems. There is almost always room for improvement or something new to test! Enjoy the process!

Hello Erik,

Perhaps it is a matter of language, because the English language is not my native language. It is Dutch.

However I really would *always* keep the twinlead off the ground, when it is outside the house.

It probably would not explode, but there are more that one reasons why I would keep the open feederline off the ground. Safety reasons, amongst other things.

We have two children, two dogs and two cats playing/running nearby the DeltaLoop I use. The antenna and feeder line are now high enough so nobody can touch them. What would happen when one of the children, dogs, cats or what ever living creature damages the feederline on the ground while running QRO...?

I would *never* advise anybody to lay the open feederline on the ground outside the shack, for various reasons.

Sorry for my bad English.

Topic: 2598 Message: 2613

Hi Hans,

"Always" and "never" convey essentially the same meaning as you are using them in this context. But I do see your point! QRO and dogs chewing transmission line and children determined to find out what that new thing on the ground tastes like are serious considerations in the environment you describe.

However, we are however no longer talking about how antenna systems operate from a technical view point and are now discussing antenna system safety. A valid topic worthy of careful consideration, but I did not understood the original question to be about RF safety. My points were not in any way accounting for any safety factors. The world is replete with examples of doing things less efficiently for greater safety.

I have nothing to say against the idea of raising as much as the antenna system as possible above prying hands and eyes. Certainly it is generally safer for those around the antenna system; especially if they are not hams. For that matter, my intent was not to advise anyone to lay their balanced line on the ground as a good general practice. It is generally _not_ the best plan.

I was only pointing out that is far different than saying "never" (or "always"). Such absolute statements are always wrong in amateur radio (irony intended ;))

My concern is one seldom knows the experience of the person asking the original question, and one can not know who may read the thread in the future, nor who is reading along with the rest of us yet remaining silent. To these persons it is unfair to make unqualified statements that you can "never" do X, or must "always" do Y. Because such extreme statements are _almost_ never true. Therefore such statements are misleading and do a disservice to the person trying to learn more about our fascinating service/hobby.

Had you pointed out you personally would never lay any transmission line on the ground for safety reasons, and you would not advice ever laying unshielded balanced line on the ground due to that contact unbalancing the feed line and almost certainly adding new losses to the antenna system, that would have been a completely different statement. That is qualifying the reasons why you recommend avoiding said actions. (And for logical and very understandable reasons, which I agree with.)

But telling a person seeking understanding to simply never/always do something, doesn't teach them very much. They need to understand _why_ we recommend doing/not doing something. As they understand the various motivations behind why we as a group do some things and avoid others

they will begin to work out new challenges for themselves without need
of our advice. This is because they are learning the principals
underlying the rules of thumb we sometimes too easily express without
qualification.

Now that we understand the different motivations we each had when making
our statements, perhaps our dear readers will be able to understand we
both meant well, but may have been better able to explain our respective
positions.

Apology accepted and apology extended in turn.

Hello Erik,

Many thanks for your kind message.

We are living on other continents, so a little misunderstanding does not have to harm the relationship.

We use to say: never say never.

I know what you mean and I have learned from your point of view.

All the best!

73,
Hans Remeeus (PA1HR)
http://www.remeeus.eu
Communication is about people, the rest is technology.

2615. Re: Twinlead on the ground

Yahoo group: SkyWires
Date: 2007-09-10 05:55:29 UTC
From: Paul
Topic: 2598 Message: 2615

And, if this tread has any more life, to bring it back to the focus I intended ... the question was about a Remote portable system, operating in some isolated mountain top - and away from crawling children and chewing dogs. I hadn't planned on open wire line - just twin lead or maybe ladderline. The idea was to play with antennas that had a little more gain, or different characteristics than a standard dipole.

I posted here because a loop was one of those "designs" under consideration. TwinLead was advised as the feeder twinlead/ladderline for best match, but to add a 4:1 balun and ocnvert to coax before getting to the tuner or rig.

I have a small 15W 4:1 current balun that seems fine for the QRP operation. But I could put it right at the antenna and go to coax immediately, or run twinlead for some X feet (say 16 feet) and then convert to coax, or run twinlead right to the rig and convert then. But if I take the last option, the twinlead my rest on the ground a bit unless I'm careful.

I'm pretty sure I can et 20 feet up so 16 feet of twinlead, then the balun, then coax the rest of the way sounds the best.

73,
Paul

PS: The size design leans more to 20M (maybe 30)and up

2616. Antenna impedance

Both these links will give you plenty of info on building very high efficiency loop antennas for the AM Broadcast band. Multi turn loops work extremely well on received signals.

The one site has a calculator to assist you in determining the number of turns, and size of your loop receive.

The advantage to building a multi turn loop is you can turn it to null our interfering noise or even an interfering station.

Thanks for the info. However am still wanted to know the input impedance of a car radio's is Hi Z or Lo Z before I can determine how the ATU should be connected to the radio. I did try to hook the radio to a homebrew ATU and neither the Hi Z nor the Lo Z output feedings to the car radio makes any noticable improvement for DX receptions.
Was told the car radio input is Hi Z (not Lo Z)at the AM band and the coaxial cable used in the car is not 50 or 75 ohms but a very low distribution capacity shielding wires. Any idea ?

The impedance of the coaxial cable that feeds the antenna input of a
car radio is 91 ohms. Presumably, that is the impedance of the
antenna input of the radio.

I hope this helps.

If you plan on using a long wire I would bring the wire all the way into the shack to the tuner
and also provide a good ground for the tuner. I would suggest a simple L-C circuit. The length
of the long wire will determine how much L you would need. If you get someone with a modeling
program to plug in your long wire then you can get your total L needed for 1.7 mhz and for .530 mhz.
You could get a fixed value for the 1.7 and then just keep adding L as you tune down to .530 mhz.
Either a variable roller inductor or an air wound that you can tap. A fixed capacitor of 9 to 365 mmf should
do the job from you antenna connector to ground. Then you should get a good match for any receive freq
in the am broadcast band. Remember, the longer the long wire the less L you would need. a 1/4 wave at
1.7 is about 137 feet. At .530 mhz a 1/4 wave is about 441 feet.

I would be interested if someone has a modeling program how much variable L would be needed to match
a 137 foot long wire to 530 KHZ. I might think about building something as well. I do like AM DX. I sometimes
listen to Trans World Radio from Bonaire on 800 KHZ in the winter months.

Good Luck, and I hope this helps you think about your project some.

Let me know how it turns out. 73's AGØK

From: VG - Vince
Topic: 2621 Message: 2621

Hi All,

Vince here, I just put up a Skywire for 40m that is about 20ft. above ground. I followed the plan of the "Loop Skywire" from the ARRL wire antenna classics and have it fed with rg 59.My run of coax is about 50ft. to the tuner. My question is, what do most of the members use for feed line? 600 ohm open wire, 450 ohm ladder line, 300 ohm tv twin lead or coax? Any help would be great.

Thanks es 73

Any of those will work - it depends if you are going to use it on just 40M - than stick with RG-59 - but RG-8 would be better. If you plan to use different band - than use ladder line - 450 ohm, 300 ohm. I use 450 ohm and it is excellent - with the 4:1 balun, it is nearly 1:1 oon 40M with my 80M loop.

Vince, I use RG59,approx 25 foot, then rg58 with my 40meter loop.
This provides a bit of impedance matching and the TX loads better
without a tuner.
I also have a loop fed with 450 ladder line for all band. Coax limits
you to monoband use where ladderline or 300 twinlead to a tuner
allows several bands to be worked.

Healthfully yours,

It's my understanding that car radio whip antennas, being rather short, are hi-Z, but have a rather low radiation resistance. Hence their efficiency is low.

The coax cable I've seen did have a tiny inner wire, making it higher Z (lower C) than normal. I wouldn't expect the radio to necessarily match the coax cable impedance because the cable is very short compared to a wavelength so matching it isn't important. Perhaps better to tailor the radio's input impedance to the antenna, not the cable.

For reception, at MW frequencies, efficiency (and getting an impedance match) is not so important as it is at higher frequencies. Even lousy antennas tend to work "well enough." When the atmospheric noise received by the antenna exceeds the electrical noise of the radio's front-end, there's not much point to improving the efficiency or the impedance match.

Andy

The input impedance of a car radio is rather high. The coax/shielded wire is used to connect the radio to the antenna and should not be looked at as an RF 'feedline'. Most car radios are designed with a high gain front end with capacitive coupling to the antenna which is omni directional. The problem with using a car radio in the house or shop is that the ideal short 'whip' antenna is close to the radio and since the radio is indoors, close to interfering noise sources it doesn't make for good AM BC reception. If you want to have reasonably noise free reception you either have to move the radio outdoors away from noise sources or locate the antenna outdoors away from noise and bring the desired RF in with a feed line system.

Assume a suitable outdoor antenna properly coupled to a low impedance coaxial feed line. The end of the feed line comes to the indoor listening location. The question is, "how do you effectively couple the feed line to the radio?". A simple L network might work .... coupled in the reverse position to the usual configuration. ie the low impedance end connected to the incoming antenna feed line and the high impedance end connected to the input of the radio (with as short a connection as possible). The L network should be of a high Q construction.

Another system would be to construct a high Q tuned circuit like the old crystal set. If you use a coax feed from your antenna you would couple it with a small link to the tuned circuit. If you are directly feeding a long wire tap it in near the higher end of the coil. The radio would also be taped in to the high impedance end of the coil using a very small tunable coupling capacitor. There are all kinds of crystal set circuits on the internet. Just substitute the car radio input in place of the diode detector and use a small variable capacitor for coupling.

The crystal set style tuner will make a magnificent AM BC receiving device in combination with a car radio. The shortcoming of course is that your antenna system will have little or no directional properties. However,

baring QRM and QRN and RFI .... if the signal exists, you will hear it.

Jim

From: knyuen88
Topic: 2616 Message: 2629

Thanks for everybody's help.
After failing different configurations with the ATU have found a simple/dirty resolution:
1. Made a simply tunable LC circuit (one side to ground and the other side directly to the longwire antenna)
2. Connect an insulated wire to the car radio input and insert the other end inside the coil(wired over a 2"dia PVC pipe) of the LC network.
3. Peak the LC network to the desired AM broadcast station(s). The sensitive/selectivity(as well and noise rejections) changed notiecably!(Jumped-up to be exact !)

Will try with a Higher Q coils later and hope the outcome can be improved even further.

From: kc0ynpmissouri
Topic: 2630 Message: 2630

About two weeks ago, I put up a 40-meter loop, but instead of making it a true horizontal loop, I used my old inverted-V dipole setup and added a 10-foot pole. Consequently, it's 30 feet high on the high side and around 10 feet high on the low side in 35 x 35' foot square, more or less (142'total length). I was wondering if anyone had tried this sloping loop setup and what kind of luck you have had. The last ARRL propagation report showed 15 days of no sunspots, but the antenna seems to work better than my old 135' dipole did when we had few sunspots a few months back, making it into Italy, for example.

By the way, I feed mine with 450-ohm ladder line into a Palstar AT1500DT tuner. Before joining the group, I read the title of all the postings looking for a title similar to mine and certainly wish the feed line thread would die a quick death. Scanning through the postings shows its a "to each, his own" situation. I just used what I had, avoided the weight of the coax, and followed the ARRL Antenna Handbook's suggestion that coax provides an easy match because of its losses, but I will probably never change feed lines to test their theory, but it would be interesting to try.

My loop is 280 ft long. It is 3 sided as I did not have 4 supports for a square loop. The apex is at 60 ft hanging off my tower and fed with W7FG open wire feedline. The other 2 supports of the loop are at about 35 ft. I have used this arrangement for 3 years. When I first put it up I used Coax. The open feeders work much better.

Does it work? Indeed it does. Check out the 3B7C online log for my call. I worked 3B7C six times with this loop. 75,40, and 30 meters.

On RTTY I used 400 watts except on 30mtrs where I only used 100 watts CW was 500 watts and the SSB contacts were 600 watts.

On 20 mtrs and up I use my Tennadyne LP beam.

The 3B7C Dxepedition is over 10,000 miles from my location. Not too shabby for what many consider a "cloud burner antenna"

This was not unusual either. I work Dx all the time with my loop and think nothing about it.

Alan,

You are going to have to explain yourself properly, this isn't an SMS message centre :)

You saying that your plot is too small for the loop or that the loop is too big for its own resonance? Are you also saying that it's only 4 feet off the ground at the centre?

Please start again and slowly explain.

Back to you.

Alan,

Don't worry, it will still work but obviously not as well as if it was 20+ ft AGL.

It's the same rule for a loop as for any other wire aerial.
Up as high as possible, don't worry if it's not a perfect square or rectangle etc.
Doesn't matter if the shape is square, round, triangular, rhomboid etc.

My loop slopes from about 50ft AGL down to 20ft AGL, works just fine.
The first loop I put up was about 20ft AGL at all 4 corners, worked very well.

To see pictures and a little more info, visit my very quick & dirty web page at the address below.

2635. Fishing poles for loop supports...

Yahoo group: SkyWires
Date: 2007-09-30 22:34:43 UTC
From: n6vl
Topic: 2635 Message: 2635

I have 4 SD-20 fishing pole blanks bought a while back from World Radio. They are 20 feet long and never used. I have wondered about using them to support a horizontal loop. I can't use the top section since it is way too thin. I've thought of using small diameter PVC tubing on the top ends to strengthen it, and larger diameter PVC tubing on the bottom ends to add extra height.

I've live in Southern California, so extreme weather conditions aren't an issue. We do have high winds here from sometimes. There is certainly no ice or snow, but only rain in the winter months.

I'd like to hear from anyone who has used fishing poles as masts for a horizontal loop.

Hi Steve,

The four poles would make a great single band full wave loop for
20M. Form them in a crossed formation. The loop could then be mounted
either as a vertical of horizontal loop. If you really want a performance
antenna for 20M you could make a MOXON with forward gain and excellent
front to back. Using them as masts would be a waste.

Topic: 2635 Message: 2637

Jim,

I once saw a photo in World Radio News where a ham used a pair of SD-20 fishing poles to hold a piece of wire in an inverted-U configuration. It was streched over and above an RV, and the poles were pulled very tight. That was a few years ago and where I got the idea of using them as masts.

I also have thought of using them in a X configuration for a 20 meter loop. The poles are too heavy for that. The diameter for the large end is at least 1 1/2 inches.

I bought 6 fishing pole blanks for a hex beam project based on a construction article. The lengths of the six blanks are shorter and about half the diameter of the SD-20 blanks.

I'd like to build a horizontal loop for my lot, but find 4 supports is going to be a problem. I live on a 60 x 100 foot lot with about 55 x 80 feet actually usable in this situation. I'd like to keep it low profile, hence the idea of fishing pole blanks.

I currently have a sloping delta loop. It is 225 feet in circumference and 40 feet at the apex. The lower corners are 6 feet and the plane of the loop is diagonal, with some droop. It is lower corner fed with open wire line. I use this antenna mostly for 40 and 80 meters.

I have a 44 foot long inverted vee dipole, similar to the one on www.cebik.com. It is fed with ladder line and is about 30 feet at the apex. This antenna performs better than my loop on 30 meters and above. It has a broadside pattern on all bands up through 10 meters where it is 2 5/8 waves in phase. Above 10 meters, it will develop multiple lobes.

I'd like to have a single antenna for 80 through 10 meters. A truly horizontal loop will fill the need. The sloping loop doesn't work well on the higher HF bands. EZNEC modeling bears this out. That leaves me with trying to find 4 supports on a small suburban lot. That is where the fishing pole idea came from. I really want to avoid 4 metal masts. Am I dreaming?

Hi Steve,

I don't know what you are using for the 30' mast for your 44' inverted V but you could extend it to 88' and it would certainly work well 80 through 10 mtrs. I used such an inverted V (100') also with a 30' TV mast for years and it worked great. If you could get the mast up another 15' it would be dynamite. I also had a 100' inverted V fed with open wire line that was mounted on a 30' TV mast on top of a 2 story house for a total of I would guess 65' and it was dynamite. I also used it as a top loaded vertical for 160m .... with water pipe as ground .... and worked the farmer's net as regularly as clock work.

Thanks Jim,

Actually the 44 foot length is there for a reason. It has broad side gain up through 10 meters. If I went with a 88 foot length, then the pattern would be broadside up through 20 meters and then break into lobes. These lobes would begin to take up a higher angle on the higher HF bands if I keep it in an inverted vee configurations.

I live on the US west coast, so a nice east-west pattern works quite well. I've had success working Alaska on 20 meters, even though it is off the end. It wouldn't be a good antenna for polar paths the way its currently oriented.

The idea of a horizontal loops doesn't prevent lobes on the higher bands. But it makes them more omni-directional. And I wouldn't be handicapped on the polar paths.

A horizontal loop would be a challenge at my QTH. I am hoping for some simple mast structures, even if only 20 to 25 feet high. The problem with the skywire is the need for multiple supports. I would to find some supports that don't require a lot of guying. It would be a lot easier if I had a few trees on my lot.

Sometimes I wonder about a smaller horizontal loop only for the upper HF bands. It would have to be a full wave on 40 to get the lower angle on 20. Acutally the 4 20 foot poles would make a horizontal loop resonant at 8.9 MHz. Maybe that might make a horizontal loop.

My sloping delta loop does great on 80 and 40.

Thanks for the ideas!

Hi Steve,

I used 4 cheap 20ft fishing poles to support a horizontal loop of 150ft approx.
It was up for 2 years here in Port Talbot South Wales without problems.

I live about 5 miles as the crow flies from Mumbles weather monitoring station which recorded winds up to 100mph while the poles were up.

I now have a bigger version of the loop up supported by 2 36ft aluminium telescopic masts with 20ft fishing poles on top of them.
The other 2 supports are 20ft fishing poles.

See HYPERLINK "http://homepage.ntlworld.com/paultom/"http://homepage.ntlworld.com/paultom/ for some pictures.
I've worked east coast US stations with 100w SSB on 160m with this one.

Paul MW0CDO.

Paul,

What wire gauge is 1 mm? I just looked at a chart, and it seems to be #18 gauge. Is that correct?

Also do you use the small diameter top section? It looks like you do in the photo. I don't want to break the small end off.

2642. Using 2 Smaller Gauge Wires in Place of Large Gauge Wires

Yahoo group: SkyWires
Date: 2007-10-02 13:29:02 UTC
From: denisnh
Topic: 2642 Message: 2642

Hi All. I remember reading (I think one of L. Cebik's articles?) that sometimes two smaller gauge wires are run together in place of a larger gauge wire that may not be available. This was only mentioned and I don't know if L. Cebik approved of this method or not.

I'm finally getting around to setting up a full wave horizontal loop for 80-10 meters. Buying wire is not an option for me at this point. However, I have a 1000 foot roll of industrial grade 18g wire laying around. It is by Chester Cable, type TEW /CSA, AWM, VW-1. It's designed for use in fairly hostile environments and the 18g wire is stranded and a silver color. I may be stainless but I'm not sure.

I realize heavier wire does have more bandwith, Besides that, how much performance would I lose if running a single 18g wire in place of 12g? If I were to run 2 wires side by side to simulate a heavier gauge wire, is it just a simple matter of taping it together every few feet? How about if it's twisted together kind of like a twisted pair? I'll be running 200 watts at the most for transmitter power.

Thanks,
Denis

2643. Feed Arrangement for Operating the Loop as a Vertical Antenna

Yahoo group: SkyWires
Date: 2007-10-02 13:55:31 UTC
From: denisnh
Topic: 2643 Message: 2643

The 18th edition of the ARRL Antenna Handbook (published 1998), page 5-16 talks about the "Loop Skywire". It mentions that by shorting the feed coax at the bottom of a vertical run, the antenna can be run as a vertical antenna??? This amazes me and I really don't understand how it would function that way. In this case, it looks as though the loop would work something like a capacitance hat? I seems a lot of gain would be lost this way but I'm no expert.

Also, in the files section of this group, Dr. Ace has an illustration and brief description of how to do this: Vertical Skywire <http://f1.grp.yahoofs.com/v1/0EACRxyDGWfhRyZvooZdhjzMty52qsuOsaY7MKaZsw\vQT_0GyrdN4U_6sEr-6oqtd8GWbSLR9R-e9VGHltbb9NbjRTSa5Q/Loop%20Antenna%20In\fo%20/loopv.jpg> He also mentions that with this method, the additional radiation length created by the vertical coax allows you to run on frequencies at twice the wavelength of the loop.

Going back to the antenna handbook mentioned above, an article immediately following the skywire on page 5-16 is a 40 meter vertical loop. I built this antenna exactly as described and it works great, but it's not an all-band antenna (although it will run some harmonics). If I were to take this antenna, re-install it as a horizontal with the vertical antenna coax, I should be able to run 80 meters on it. I would probably use a good quality coax such as rg-213 for the vertical element.

Any ideas on how this would perform in comparison to the conventional skywire with a ladder line feed?

Thanks,

Denis

2644. Re: [SkyWires] Feed Arrangement for Operating the Loop as a Vertical Antenna

Yahoo group: SkyWires
Date: 2007-10-02 17:59:01 UTC
From: Erik Weaver
Topic: 2643 Message: 2644

Hi Denisnh,

I'll comment on a little of this, but I can't answer all your questions. Maybe others will fill in the blanks for you. The 2nd best answer is to model the two antennas, which I have not done, and the very best way to judge is build them both on your side and compare, but who does that? I've not done either, but I have ran my own horizontal loop for a few years. Third best is to build the antenna system on paper and calculate some of what can be expected. That is what I'll discuss below.

With regard to feeding the loop at the base, according to my reading it is exactly like running it as a vertical with a large capacity hat. I tried that once or twice just to see if it worked. It did, but so did the loop used as a loop, so I only tested it and then then never used it as a vertical again. Also mine had very little vertical component to it so I didn't think it was an important difference in my configuration. (I took down my loop last winter when one of the corner supports broke. I've not put it back up yet.)

I've read many people run a loop this way to get on 160-meters. The ones I remember were using balanced feed line. You just connect both balanced feed line wires to the same output terminal on your XCVR (or transmatch/amp). The other (now unused terminal) is connected to an earth ground. The balanced feed line is now an active antenna element, and in a vertical orientation. Above this is the horizontal loop. It does act as a cap-hat. If you go back to Cebik's web pages I know he used to have several pages of info on cap-hats. That will provide much more info about them than I. (The same is true of antennas in general; you have found a very good and reliable source of antenna theory -- stick with Cebik -- he's one of the good guys!)

Remember, in a balanced feed line, current is opposite in both direction of flow and locations of min/max values. "Equal and opposite." If you recall your basic EM (electromagnetic) theory (found in the ARRL Handbook if you need to review it) that means the EM fields cancel one another, and therefore the balanced feed line does not radiate as does an antenna wire. When the two "legs" of the balanced feed line are connected to the same terminal at your station, this "balanced" condition no longer exists. Both wires now carry the same EM wave, having their min/max values (of both current and voltage) at the same locations along the wires, and the EM wave is moving in the same direction at the same time. Therefore, the wires now radiate as an antenna element. They no longer cancel each others EM field, so they radiate.

With regard to using balanced feed line or coax, the primary considerations are the surroundings and number of bands planned for use (which ties directly to transmission line loss).

Surroundings -- If you are weaving around and between a lot of material, especially metal or magnetic materials (including items such as electrical lines that create EM fields), then coax is best. It has shielding so it is not affected by that metal water pipe you just taped your transmission line to running across the basement ceiling ;) Recalling the balanced nature of balance line (whether open, twin lead, window, ladder, etc.) which is why it behaves as it does, if you disturb that balance, and unbalance it, at that point it begins to behave as a radiating element of your antenna. Generally not such a good plan in your basement ;) So when the surroundings will upset the balance of balanced feed line, use coax.

That's the easy part. It is pretty much straight forward.

Number of bands & transmission line loss -- This gets more complicated. Let's first briefly compare balanced line to coax. Balanced line (provided you do not allow it to become unbalanced) offers very little loss of energy over long distances. Nor does it radiate. This is due to the "equal and opposite" direction and magnitude of the EM energy flowing along the balanced line. By altering the diameter of the conductors and the distance between them, you can alter the impedance of this balanced transmission line. Generally amateur radio operators use something around 450-Ohm line, but one will still commonly find impedance values from 300- to 600-Ohms.

If you know the feed point impedance of your antenna across all the bands you intend to operate it upon, you can determine what impedance is best. I believe most of us just pick a specific type of balanced line (and therefore value of impedance) for entirely different reasons, such as what we happen to have, can easily make, or is currently on sale.

If you are running the transmission line in the clear, and want to minimize transmission line loss, and maximize the number of bands you can work, then balanced feed line is a good choice. "In the clear" means no closer to anything metal than one-width of the balanced line. More clearance from object is better. If you can ensure several widths-distance you should find it performs quite well. Maximizing the number of bands you can use means using a transmatch (aka antenna tuner) or setting up a series of tuning stubs, or switchable lengths of transmission line. Each of these effects impedance values. Pick your favorite method. (I'll not discuss these options here, as I think it is off-topic, and can be a lengthy discussion to describe fully. And many articles written about each option.)

Coax can run right along metal and not be affected by it. This is great is tight quarters, and it is often readily available which is also convenient. It too is available in a range of impedances, generally from 50-Ohms to 125-Ohms from specialty stores, and most commonly in either 50- or 75-Ohm impedance. The value of impedance is due to the size and

spacing of the inner conductor relative to the shielding, or braiding, wire surrounding it. Some of it is rated for underground routing, and some has high UV protection ratings. It can be run in parallel as a balanced line and some hams use it in this fashion to go through walls and maintain a balanced feed line while doing so (this is described in the ARRL Antenna Book, to which I think you said you have access, so I won't describe this further).

Coax has a special condition. If the coax impedance exactly equals the impedance of both the antenna and the XCVR there will be no loss along the transmission line (coax), other than a small amount of attenuation which is always present in real life. In all other cases, one should consider the amount of loss in the coax for each band you intend to operate upon. It can be quite high (bad), which is in stark contrast to balanced line in which this is pretty much not even an important consideration.

The ARRL Antenna Book discusses this topic. They have charts and tables of data which will allow you to estimate loss at various frequencies. If you evaluate the highest frequency for each band that will give you the worse-case condition for loss. Repeat this for each band you are interested in working.

I've been avoiding this part because too many people get too upset by it. Those charts and tables require you to know your swr.

VSWR is voltage standing wave ratio, and ISWR is current standing wave ratio. They are both the same value. One measures current and one measure voltage and then uses the resulting values in the same formula. They have the same ratio one to the other, so the resulting swr value is the same. So when people say VSWR just think "swr is swr" and you'll be fine. Neither ISWR or VSWR is better than the other, you just need to use the one your meter is designed to measure. Most devices measure voltage, so most often we are using VSWR in our calculations. For our purposes, they are the same thing: swr.

SWR -- Standing Wave Ratio. Basically two sine waves running in opposite directions at the same time. The first ("incident") sine wave moves from the XCVR to the antenna when you are transmitting. If the antenna has a different impedance than this sine wave (which is created by the interaction between the original impedance generate at the transmitter and the transmission line through which it is moving) a portion of the incident wave will reflect off the antenna and reverse direction. It now becomes the second sine wave, the "reflected" wave, and moves from the antenna feed point back toward the XCVR.

Freeze frame. You now have one waveform moving from the XCVR toward the antenna feed point, and a second waveform moving from the antenna feed point toward the XCVR. They each repeat their highest and lowest points of their sine waves at regularly repeating intervals during this trip. They will be different; each will have it's high and low at different points along the transmission line. But they don't behave as two

different things inside the transmission line, they combine as they pass one another to form a new "combined" waveform. If you were able to see this running along the transmission line (either coax or balanced) they would appear to be standing still. This is why it is called a Standing Wave. The swr is a comparison of the highs to the lows, hence, the term Standing Wave Ratio.

That is all swr means. We could choose to measure the two sine waves formed by the voltage, or the two formed by the current, traveling along the transmission line. Both would have the same swr after we solved the formula (but they would use different raw numbers). It is similar to asking what is the difference in ratio between 2:4 and 5:10? None, of course: 2 goes into 4 twice, and 5 goes into 10 twice, therefore both have the same ratio of 2:1.

However, due to the physical properties of coax and balanced line, they behave differently in terms of energy lost (mostly as heat) while traveling along the transmission line. Balanced line loss is generally much lower than coax over the same distance. You will see this on those charts and tables spoken of earlier.

(Not to be taken literally, but if you need a mental picture to sort this out, remember that heat is generated as energy travels through the wires of your transmission line. Open wire has no insulation, and ladder line has very little, so it traps less heat. Coax has a lot more insulation inside it, the heat can't escape and it gets hotter, faster, thus causing greater losses. Please, don't take that as what really happens, but if that image helps you remember the gross differences between the two types of transmission line, use it for that limited purpose. If you don't need that picture, forget I mentioned it.)

SO WHAT?!?!

Find the swr for the highest frequency on each band you intend to use your antenna on. Now go to those charts and tables in the Antenna Book and figure out the losses inside the transmission line. You will quickly see that a 10:1 swr isn't a great loss of power on balanced line, but is a large loss of power in coax.

Does that matter?

I don't know. Which, and how many, bands are you using the antenna on? What is the swr there? How much loss of power is that? Does that matter to you, or not? Those are the questions you have to answer to know if this is important to you for this particular antenna system. Once you crunch the numbers I suspect you'll quickly make up your mind.

Remember too, if you use a transmatch (aka antenna tuner), which is normal for this kind of antenna, you will not alter the swr along the transmission line between the transmatch and antenna feed point. So any loss calculations for that segment of the transmission line will remain the same as when the transmatch is not being used. This isn't good or

bad, just keep it in mind as one of the variables.

My Loop:

My loop was roughly 250-feet and triangular in shape (horizontal). Why? That is where my supporting trees are located. It went out my window as balanced line from my transmatch. Immediately it transitioned into my antenna wire (bare #14 stranded copper). It went up into the nearby tree outside my shack window, to a height of about 12 to 15 feet. At the bottom it was ladder line, quickly spread to about 3-feet apart, and by the top it spread out to about 4-feet distance between the two wires. They were balanced, but the distance steadily grew farther apart, and did so abruptly at the very bottom (perhaps disturbing the balance, near to the planet, thus inviting ground loss -- yet another topic). I never tried to calculate, and certainly never tried to measure the impedance change along this part of the antenna/feed line.

At the top of this vertical segment (first tree by the shack) one wire ran to a sycamore tree in the back yard to a height of about 40-feet, and the other wire ran from the shack-tree to a pine tree in the side yard to a height of about 50-feet. So my triangle loop was tilted somewhat. Highest corner to the east, lowest to the west, and middle corner toward the north.

My very first contact was in Australia, and I often used it to participate in a state-wide (MO) traffic net on 80-meters and sometimes 40-meters.

I have no idea what the swr was, nor what the losses were. I'm confident the losses were low because my transmission line was both balanced and very short. So regardless of the swr and line loss nearly all the energy transmitted to the antenna system was radiated. Really the only points of concern were transitioning under the window and that abrupt splitting of the ladder line so close to earth. Neither was optimal.

In other words, I'm confident it was efficient, meaning, nearly all the energy I put into it radiated from it, and very little was lost in the antenna system (transmission line and transmatch in my case). If you can achieve high efficiency you don't need much else. This is one reason dipoles are said to work so well. They are highly efficient.

I hope this helps a little. I recommend studying those transmission line loss tables in the Antenna Book. Once you know or estimate your swr and know the particulars of the transmission line (look up the "characteristic impedance" for your transmission line -- it should be readily available from the manufacturers data), you can see for yourself how much energy you will lose in various alternate systems. Then it is simply a matter of choosing the one that provides the overall best performance at the bands you prefer for the price you are willing/able to pay.

Have fun! You can learn a lot of good theory and real hands-on
application through this project. Antennas remain one of the most
accessible aspects of amateur radio we can easily and affordably play
with, so enjoy yourself, and be sure to let us know how it turns out for
you!

Hi Steve,

I have no idea what US wire gauge 1mm is.
The 1mm includes the insulation, but as mentioned on the web page it's incredibly tough.

Yes I do use the thin top section with the eye fitted, the wire passes through the eyes.
So far, no breakages.
When the wind blows, and boy does it blow!, the flexibility of all the poles allows the antenna to move in any direction and nothing breaks.

I've had a Butternut HF5b, a 5 ele Tonna for 6m and 13 ele Tonna for 2m trashed by the winds here.
My Butternut HF6v has survived so far as well, another very flexible antenna.

Paul MW0CDO.

Paul,

What wire gauge is 1 mm? I just looked at a chart, and it seems to be #18 gauge. Is that correct?

Also do you use the small diameter top section? It looks like you do in the photo. I don't want to break the small end off.

2649. Re: Feed Arrangement for Operating the Loop as a Vertical Antenna

Yahoo group: SkyWires
Date: 2007-10-03 14:39:38 UTC
From: denisnh
Topic: 2643 Message: 2649

Hi Erik,
WOW! What a great reply! Very detailed. You should save this as part of the manuscript for your book. What? You're not writing a book? Well you should!

The night before I submitted my post, I read a few of Mr. Cebik's articles on feedlines. The charts in the article are quite remarkable when comparing coax against parallel lines of various impedances. The curves for parallel lines all hug the bottom of the chart where the favorable SWR and other factors are, while the coax lines soar skyward surprisingly fast, which concurs with your post.

I have not used any modeling software. Just not enough hours in the day, as most of my time has been spent trying to survive since my career did a crash and burn. All my HF antenna experience is in receive only antennas for shortwave. I've been dragging my feet on getting my General Class license but finally decided to go for it this month. Of course, I had masterd 5 wpm CW just in time for that requirement to be abolished. :-)

Some people seem to put all their faith in the modeling software. Whatever works for them, but I would never take a computer model as being 100% accurate. To me, the model really has to be built in 3D to prove it works. And this is coming from a former software engineer. :-) I've read about too many antenna designs that required adjustment contrary to the modeling data to get them to work. But modeling is a great start, and at least 90% accurate in my opinion.

The idea of using coax was more of a "fast start" idea while I fiddle with the antenna and try to improve it. I don't even know how much longer I'll be able to keep this house and that has zapped a lot of my motivation to build anything. What the heck though, and after reading your reply, I believe I will go with the 40 meter loop and orient it as a horizontal with paralell feedline.

Regarding running the line into the shack, shorting the wires and connecting them to the rig, there are a few reasons I can't do this. For one, there are children and unknowing people in the area that may get zapped if they are able to touch the wires. My ham station (or what's left of it) is in my basement office. I need to run the line vertically to about 8' above the ground, make the short at that point, and install a matching network either on a pole or tree in a PVC junction box. The ground wire would go there also, and then I need run the ground and an insulated feedwire the remaining distance to the ground, bury it and slip it through the side of the house

into the shack.

That's what I need to research next: Building a matching unit.

Wouldn't running the vertical radiators into the shack introduce a lot of RF there? I'm also wondering about the effect of having two vertical radiating elements so close together and the effect they would have on each other. Another thought would be to have a pulley located at the feedpoint where I could quickly lower the antenna and switch to coax for the vertical element and back to paralell feedlines for loop operation, but that may be a lot more trouble than it's worth.

One other thing to mention is that I have a decent antenna tuner. How this would work with a matching network is something else I'll have to research. Putting the tuner outside is not practical. Ideas, anyone?

Thanks again for the info, Erik!

Denis

From: Paul MW0CDO
Topic: 2635 Message: 2650

Hi Bob,

I don't have the remains anymore, it got trashed 5 or 6 years ago and I gave the remains away.

Shipping would be expensive from the UK anyway..!

Cheers,

Paul MW0CDO.

Hi Steve,

I have no idea what US wire gauge 1mm is.
The 1mm includes the insulation, but as mentioned on the web page it's incredibly tough.

Yes I do use the thin top section with the eye fitted, the wire passes through the eyes.

So far, no breakages.
When the wind blows, and boy does it blow!, the flexibility of all the poles allows the antenna to move in any direction and nothing breaks.

I've had a Butternut HF5b, a 5 ele Tonna for 6m and 13 ele Tonna for 2m trashed by the winds here.
My Butternut HF6v has survived so far as well, another very flexible antenna.

Paul MW0CDO.

Paul,

What wire gauge is 1 mm? I just looked at a chart, and it seems to be #18 gauge. Is that correct?

Also do you use the small diameter top section? It looks like you do in the photo. I don't want to break the small end off.

73,

Steve N6VL

Hi Denis (I thought "Denisnh" was a unusual name! heheh)....

Comments in body below....

...snip...

> The curves for parallel lines all hug the bottom of the
> chart where the favorable SWR and other factors are, while the coax
> lines soar skyward surprisingly fast, which concurs with your post.

Cebik's web pages are filled with useful information -- time there is well spent. The rapid rise of losses in coax under high swr conditions is in sharp contrast to the low losses generally found in balanced ("parallel") feed line. It is one of the major differences between them. About the only negative that comes to mind with balanced feed line is the need to carefully route it; so it isn't practical in all cases.

Here's something else to consider....

Remember first the rare "special case" where impedance is the same everywhere in the antenna system (XCVR, transmission line, antenna, etc). With the exception of a tiny loss of energy as electrons rub against one another (this loss due to friction is usually insignificant in the typical amateur radio installation), nearly all the RF ("Radio Frequency") energy generated by the XCVR radiates from the antenna as radio waves. This is our goal of course.

By the way, I usually speak in terms of transmitting a radio signal and trying to send it out into the world (our "Hello World!" message), but the efficiencies (or lack thereof) work exactly the same in reverse. In other words, the antenna has the same gain (or loss) as a receiving antenna, as it does when transmitting. So our rare special case antenna will also deliver all the RF energy it collects to the receiver (less friction/heat lost to move the electrons -- which can never be avoided in the real world).

Now when the impedance is one value on the transmission line (and it doesn't matter what kind of transmission line), and the impedance of the antenna is a different value, some RF energy is reflected off the antenna feed point, back to the XCVR. How much is reflected depends upon how great the difference is between the impedances.

There is a difference in behavior at the antenna feed point between a coax fed antenna and a parallel line fed antenna.

Balanced (parallel) line only offers a two-way path between the antenna and the XCVR. Coax may offer a third pathway -- along the outside of the shielding (aka "braid") of the coax. This is because the higher the frequency of alternating current (like RF) the less deeply the RF penetrates into the conductor -- this is called "skin effect". RF doesn't penetrate very deeply into the conductor; it travels along the outer-most surface, shallow enough in fact that one wave of energy can travel along the inner surface of the coax shielding while a second wave travels along the outside surface of the same coax shielding, and the two will never meet. Therefore, coax can offer three conductors to RF: along the inner conductor; along the inside of the coax shielding; and along the outside of the coax shielding. We desire the first two paths, but we do not (usually) benefit from RF flowing on the outside of the coax shield.

Since balanced (parallel conductors) transmission line (aka feed line) is constructed of only two wires (which may be either stranded or solid wire), the reflected wave (that energy which is reflecting from the antenna feed point, back to the XCVR) has only one return path available to it -- it returns ("reflects") back along the same conductor that it originally traversed. This is a simple condition, and no "balun" (more accurately "bal-bal" for "balanced-to-balanced" in this case) is required to maintain the desired energy pathway between the XCVR and antenna.

("Balun" is a conjunction of "balanced" and "unbalanced" identifying a transition from a balanced transmission line to an unbalanced line. "Unun" identifies transitioning from "unbalanced" to "unbalanced" line. "Balbal" identifies transitioning from "balanced" to "balanced" line. Depending upon the design, this transformation may occur at a number of different ratios, of which 1:1 and 4:1 are the most commonly used.)

This simple two-way path is not always the case when using coax. If the impedance mismatch is great enough, some fraction of the RF will find an easier pathway flowing along the outside of the coax shielding. This can cause problems such as RFI (Radio Frequency Interference) and inaccurate readings on our meters (which are designed under the assumption RF will travel along two paths, not three). Suffering a bad case of "RF on the feed line" may cause RFI to affect other electronics in the area, provide false swr readings, and cause "RF bite" on our microphone. This is often caused by RF radiating off the outside of the coax, instead of the antenna. (Although in some cases problems may exist even when feed line radiation has been eliminated. RFI can be a difficult puzzle to solve.)

Enter the balun. By "wrapping" the coax with a much greater impedance than the antenna feed point, we keep any stray RF from moving onto the outside of the coax shielding. (Targeting a much greater impedance on the outside of the coax than inside it.) To the degree this is successful, RF may only travel onto the antenna, or back along the inside of the coax to the XCVR. (On either the inside of the shielding or along the surface of the center conductor. No RF travels along the

core of the center conductor, due to skin effect.)

Once again we have only two pathways for the RF to travel allowing our equipment and antenna system to behave as intended, and within predictable parameters. This is why a balun may be useful at the feed point of an antenna when using coax transmission line. It is also why, unless the coax impedance is very close to equaling the antenna's impedance where they meet (the feed point) a feed point balun is advisable when using coax.

Reflection, re-reflection, and re-re-reflection....

Recall the transmitted RF wave traveling along the transmission line to the antenna feed point, and not finding a perfectly equal impedance, some bounced back toward the XCVR in the original direction.

Now the reflected wave races toward the XCVR. Some of it was absorbed by the antenna, and some has been lost in the transmission line (heat/friction). So it isn't exactly at the same impedance when it started, and it has been altered in other ways too. Namely the "phase" of either the voltage or current has been shifted. To learn more about this, "Reflections II" by Walter Maxwell W2DU is a great book! Highly recommended! If you see one at a hamfest, buy it!

We'll skip over exactly what and why this change takes place (entire books have been written about just that!), but the RF wave is different than when it left the XCVR, and as a result, it will "bounce" (or re-reflect) off the XCVR, and move in the original direction again. It is re-reflected back toward the antenna feed point.

The re-reflection point will be the transmatch instead of the XCVR if a transmatch is being utilized. Either way, the RF wave will bounce back and forth, reflecting, re-reflecting, and re-re-reflecting, and so on, until it either all eventually escapes out the antenna or is absorbed as heat/friction in the transmission line. (In truth, it is always the sum of both events -- what isn't eventually changed into heat in the transmission line escapes the antenna as radiated RF.)

As the swr increases, and as the inherent loss of the transmission line increases (lower in balanced line; higher in coax), more of the RF energy is lost as unproductive heat/friction, and less is available to radiate from the antenna as a useful radio signal.

This is why high swr on balanced feed line isn't all that bad. Most of the RF energy will eventually "bounce" out of the antenna anyway. It doesn't really matter if it makes it out the very first trip, on the sixth, or 16th. Radiated is radiated. The person receiving your radio signal will never know if they are hearing the very first wave or a re-reflected wave. It just doesn't matter after the energy escapes the antenna.

Escaping the antenna is the trick!

And that is where coax may not work well in the same situation. Coax, suffering much greater losses to the RF as it traverses along it ("attenuation"), simply absorbs too much of the RF as it bounces back and forth, especially under high swr conditions. There isn't much left to escape out the antenna.

All of which leads to the generalized conclusion that wire antenna elements fed by balanced transmission line, operate very efficiently even under high swr conditions. That is why these types of antennas (from dipoles to loops) have built a reputation as practical multi-band solutions for many amateur radio operators. The only stumbling block is transforming their wide ranges of impedance into something close to a nominal 50-Ohms resistive (meaning little or no reactance) to match our "modern" (meaning non-tube) XCVRs. And that is precisely what a transmatch is designed to accomplish.

> All my HF antenna experience is in

Heheh, yes, that sounds just about right! ;) Welcome to HF! And welcome to the world of transmitting antennas. They can be a lot of fun!

> Some people seem to put all their faith in the modeling software.
> Whatever works for them, but I would never take a computer model as
> being 100% accurate. To me, the model really has to be built in 3D
> to prove it works.
...snip...

Precisely! It can save a lot of time by eliminating very bad or very unlikely designs, but it is almost impossible to fully model the environment in which the antenna will be built. So you have to actually build it and test it at some point. This is like other rules of thumb. Take any of the "formulas" for determining the proper length of antenna elements. They all say to start too long and slowing trim it to a proper match.

Whether a formula for a simple dipole, or a computer model of a loop or beam, the idea isn't to make the perfect antenna on paper and then reproduce it exactly in the real world. It is to "get close" and possibly avoid some time lost in fiddling around. Beams are a good example. You can play with the modeling software and try out different element combinations and get an idea of the resulting envelopes and feed point impedances. This saves a lot of time, but ultimately you have build it and tune it to your exact site.

> ...snip... What the heck though, and after
> reading your reply, I believe I will go with the 40 meter loop and
> orient it as a horizontal with paralell feedline.

Adding a transmatch (aka antenna tuner) between your XCVR and antenna will most likely allow this to become a very usable multi-band antenna.

Every antenna displays its own range of impedances, and these vary on each band. (This "impedance" is more properly called "complex impedance" because it includes some reactance.) Very low impedances are typically difficult for many transmatches to "match," but any extreme value of complex impedance may fall outside the range which a given transmatch can "match." ("Match" means transforming the existing complex impedance, on the antenna-side of the transmatch, into an impedance (with little or no reactance) close to that which the XCVR is designed to work into.)

But there are workarounds, such as matching stubs, and other solutions. (See below.)

> Regarding running the line into the shack, shorting the wires and
> connecting them to the rig, there are a few reasons I can't do this.

> into the shack.
>

If you are married to the idea of having the vertical option, this may be true. You might consider a simple 30-amp automotive relay too. Put 12-vdc to it and remotely control that shorting switch.

I'm not sure I'm picturing this properly. Where is the antenna feed point in relation to your shack? Pretty much right above it, or 50-feet distance after you get outside the house?

I'm wondering if we're talking about a longer run from the shack to the antenna feed point, like 50- to 100-feet or more, or a much shorter run like 20- or 30-feet?

Also, consider getting outside in as short a run as possible, and making a longer run of ladder line to get to the antenna feed point. I had one dipole for which I ran 300-Ohm twin lead transmission line half way around my house under the overhang of the roof.

> That's what I need to research next: Building a matching unit.

There are two different kinds of impedance matching devices. One is fixed, and the other is variable. Each has a number of different designs that may be implemented.

Fixed impedance matching devices work extremely well with single-frequency antenna systems. If broad enough they can work reasonably well for an entire amateur radio band. But I doubt you'll

find a single fixed impedance matching solution for all bands.

There are a couple options that come to mind to get around this limitation....

Easiest is to use a variable impedance matching device instead. A transmatch ("antenna tuner") in other words.

But that is not the only way to transform impedance with some variability. You could make a set of "matching stubs" which are typically lengths of coax cut to a specific size and either shorted or left open on the far end, with the other end connected to the antenna system using a "T" connector. If you have enough of these you could switch in the proper one to alter the impedance being presented to your XCVR to within a range acceptable to it, thus allowing it to load the antenna system without causing your XCVR damage.

Similar to this is using a number of lengths of coax to once again alter the impedance presented to the XCVR. Rather than connecting these with a "T" connector, instead you simply add or subtract them from the total length of transmission line. This in turn alters the impedance "seen" by the XCVR.

Of these, the simplest and easiest solution to implement is using a transmatch. Then if you do find a certain range of frequencies that you still cannot match on a given band, add a 1/8-wavelength (WL) length of transmission line (between your transmatch and antenna) and see if you can then match your system. If not, add another 1/8-WL, and try again. After you add 8 of these 1/8-WL lengths of transmission line you will be right back where you started (having added one full wavelength of transmission line). In many cases, one of these will shift the impedance "seen" by your transmatch enough to allow it to work.

Picture a one full sine wave, running horizontally left-to-right, which represents one full wavelength. As you travel up and down and up again along this sine wave, you are moving through changing values of impedance. (The actual values will be different for each frequency, of course.) Once you get to the end of one sine wave, and begin the next sine wave, the pattern repeats, and continues to do so until you reach the end of the transmission line (at the antenna feed point, transmatch, XCVR, amplifier, etc).

Now imagine a pair of horizontal lines, one somewhere between the middle of the sine wave and the tippy-top, and the second one somewhere between the middle of the sine wave and the very bottom. The area between these lines, crossing through the center-line, represents the range for which your transmatch will successfully transform the existing impedance (that falls between your two lines) into something fairly close to 50-Ohms, zero reactance. The area of the sine wave curve above and below these two lines is beyond your transmatch's ability to "tune your antenna."

Pick a point at the very tippy-top of the sine wave. Your transmatch cannot transform that impedance. By adding a short section of coax (between the antenna and the transmatch) you effectively move that point forward along the sine wave curve some distance. If that point now falls somewhere between your two lines, the transmatch can transform that impedance into something your XCVR will load into: in popular parlance, the antenna is now "tuned."

If that point did not move far enough, and it still lies above the upper line, you will have to add another short section of coax to move that point ever farther along the sine wave curve. In the example I used above you have 8 short pieces of coax, each 1/8-wavelength long, so if you end up adding all eight pieces, you are right back where you started. At some point you will find a value of impedance with which your transmatch can work, or you will have determined that transmatch is unable to tune that antenna system at that frequency.

(Adding or subtracting 1/8-WL sections is a reasonable tactic, which is why I cite that as an example. You only have to remember those lengths are (1) electrical lengths, not physical lengths; and (2) a 1/8-WL piece of coax for 20-meters, will be close to a 2/8 (or 1/4) wavelength piece of coax on 10-meters, and only a 1/16th WL on 40-meters.)

> Wouldn't running the vertical radiators into the shack introduce a
> lot of RF there?

Yes, if they are in fact radiating RF, that is likely. The idea is to avoid that from happening if they are supposed to be feed line, and if you do want to use them as vertical antenna elements, they only radiate where you wish to do so.

There are two basic kinds of transmission line: coax and balanced. If using coax, refer back up to the discussion about the "third path" for RF to travel along the outside of the coax shielding. If that takes place, then yes, you may experience a lot of RFI. If not, there should not be any problem. This is exactly where coax excels! Coil it, sit on it, tape it to a copper water pipe, if the RF is contained inside the inner-side of the shielding you will be fine.

This means using a properly designed balun at the antenna feed point, and properly transforming impedance at your XCVR. If the antenna has a properly working balun (so not RF gets on the outside of the coax at the antenna feed point) but you have a large impedance mismatch at the XCVR, you will allow RF to escape onto the coax there, and for the same reasons as it may do so at the antenna feed point. If you put a second properly designed balun at the XCVR feed point, it won't hurt anything, and if the impedance should become unbalanced for some reason, it will isolate the coax feed line.

It is also possible at some frequencies the coax will interact with your antenna. This may occur if it is of a proper length to be a harmonic of the RF, for example.

Balanced line will eliminate this RFI problem, however, since you are routing this inside and through a building it is quite likely at one or more points it will become unbalanced, and then your problem will be even worse. At that point it will be an antenna element. Generally not the goal of transmission line! ;)

IF you can ensure a minimum of one-widths distance (more is better -- see first email) from everything, this may then work. But that is unlikely. So using balanced transmission line indoors isn't generally a good choice. (Which is why so many people use coax indoors, of course.)

There is a third option. Use coax in a different configuration. This is described in your ARRL Antenna Book. You will cut two (exactly) equal lengths of coax. If you are using parallel line outside to feed your antenna, use the highest impedance coax you can find. The highest I've found online at the larger coax dealers was 125-Ohms. But if you can only get 50- or 75-Ohm, go ahead and use that. It won't be the end of the world or anything!

Now, tape these two lengths of coax together, or use cable ties, etc. This doesn't affect how it will work, but does make it easier to handle. You will use the two inner conductors as balanced parallel feed line. At each end solder the shielding together. On the outdoor-end you will leave this shielding "floating" (not connected to anything other than each other -- but do weather proof them so no water gets inside the coax). Indoors in your shack you will connect the shielding to your station ground. Connect the two inner conductors exactly as you would any other balanced parallel transmission line. You have created a shielded balanced line! This can be routed as if it were coax. Losses will be greater than with normal balanced line, but if the length of the run isn't too long it shouldn't be excessively high.

If you have a remote transmatch and match impedance outdoors between this coax-shielded-balanced line and the regular open line it should have pretty low loss (because the impedance can be closely matched to what both the paired-coax and XCVR are designed to work into).

The easiest way to get through a building, however, is to just use a high quality, low-loss coax and keep that run as short as possible. Refer back to those tables to calculate the loss at various frequencies.

Those are your major options, and each of them if done correctly, should not cause RFI problems.

> I'm also wondering about the effect of having two
> vertical radiating elements so close together and the effect they
> would have on each other.

Radiating? Or parallel conductors??

Radiating elements do of course interact with one another. That is how beams work. If you mean parallel conductors, the best plan is not allow them to radiate.

If you mean as radiating elements in a vertical antenna, study the Antenna Book in the section they discuss phased vertical elements. As I recall when they are quite close together the envelopes mostly overlap and there isn't much "phasing" taking place (no directivity, etc). *IF* I recall this correctly I don't think you will need worry about them adversely affecting one another. They should mostly behave as one vertical element on the HF bands.

> Another thought would be to have a pulley
> located at the feedpoint where I could quickly lower the antenna and
> switch to coax for the vertical element and back to paralell
> feedlines for loop operation, but that may be a lot more trouble than
> it's worth.

I'm too lazy for that! :) It is beginning to sound like work. Your mileage may vary.

> One other thing to mention is that I have a decent antenna tuner.

Good news! I suggest using it! :)

Connect it at your station with whatever length of coax best fits to your XCVR. That is the proper length for that coax. You want it short so you're not tripping over it, but not so short it is a problem to get to the back of your XCVR or any of the other connections.

You see, coming out of the back of your transmatch and going to your XCVR (if the transmatch is properly adjusted) the impedance will be very close to that which the XCVR is designed to work into. We haven't mentioned this, but I am assuming you have a "modern" transistor-based XCVR. (If you are using a tube-based XCVR much of what I have said will be somewhere between wrong and just unnecessary.) This means your XCVR wants to "load into" something close to 50-Ohms. So use 50-Ohm coax to connect the transmatch and XCVR and you will have nearly a perfectly matched impedance between them, at the designed impedance of the coax, so therefore there will be almost no loss along that length of coax, and it can be any length you desire, and not affect the impedance as a result of its length. (Within reason -- if you use a mile of coax, even the small losses will accumulate over such a long distance to adversely affect the system.)

This is because all the impedances are the same (the coax, and both "loads" on either side of it -- in this case the transmatch on one side and the XCVR on the other). Therefore you can take a long length of coax, measure the impedance, and you will find the same impedance at any other point along that coax. It is experiencing that "rare special condition" spoken of earlier.

So we now know there will not be any appreciable loss going from the XCVR to the transmatch. We also know once we get outside and onto the balanced (parallel) transmission line, there will be only minimal losses. So the only "tricky" part is getting from the indoor transmatch to that balanced line outdoors.

By the way, if you use insulated 450-Ohm ladder line as your outdoor parallel transmission line, that should eliminate the issue of kids grabbing the line. Especially, if as you say, this is 8-feet or so above the ground and pretty out-of-sight, out-of-mind.

You have not said how far the distance is between your shack and the proposed antenna feed point. 50-feet? 500-feet? There is a world of difference between these. If you are talking about less then 100-feet, I'd just buy really good low-loss coax (RG-213, LMR-400, Beldon 9913, or better -- something like that) and route it outside, and connect to my ladder line there.

Here's some typical losses for 100-feet of coax (double the losses for 200-feet and cut i in half for 50-feet):

COAX
Loss RG-174 RG-58 RG-8X RG-213 RG-6 RF-9913
1MHz 1.9dB 0.4dB 0.5dB 0.2dB 0.2dB 0.2dB
10MHz 3.3dB 1.4dB 1.0dB 0.6dB 0.6dB 0.4dB
50MHz 6.6dB 3.3dB 2.5dB 1.6dB 1.4dB 0.9dB
SOURCE: http://www.radiobooks.com/products/techinfo/coaxloss.htm

Attenuation (Loss, dB per 100 feet)
COAX: 30-MHz: 50-MHz:
RG-174 5.5 6.6
RG-58 2.5 4.1
RG-8X 2.0 2.1
RG-213 1.2 1.6
LMR-400 0.7 0.9
9913 0.8 1.5
SOURCE: http://www.universal-radio.com/catalog/cable/coaxperf.html#atten

You will note there are some minor differences in sources, but they generally agree. To really know for certain you have to measure your coax. There can be differences between production runs.

Still, if you buy 9913 and use 100-feet of it, you are somewhere around 1-dB or so of loss (as we know, this will be worse as swr climbs, so take that into account as well). As you may recall, a 3-dB loss is a reduction of half your power: 100-watts becomes 50-watts.

If you are only talking about a 30-foot or a 50-foot run the losses will be less. So if you use coax to get outside, and you are using the transmatch indoors and you want a multi-band antenna, do try to keep the coax run as short as possible. We know you'll have 8- to 10-feet of coax to get up away from the kids. Add to this whatever length is required to reach your transmatch. Then you can calculate various losses for each band at various degrees of mismatch.

> How this would work with a matching network is something else I'll
> have to research. Putting the tuner outside is not practical. Ideas,
> anyone?

That will work. You can use more than one impedance matching system at once. The end result is simply a sum of the interactions. We do so all the time anyway because transmission line itself is transforming impedance. In fact, one way to think of a transmatch is as a big variable length of coax shoved into a tiny black box! ;)

As I see it, your biggest issue is getting out of the basement and 8-feet above earth. That is where it seems you are most likely to suffer the greatest losses. If you use coax, then high swr will hurt. It you use ladder line --if that is possible-- you have to be very certain it remains balanced. Or use shielded balanced line. It is made commercially, so the larger transmission line suppliers may carry it, or know where you can order it.

But if you are able to exit your house quite close to your station, and the antenna feed point is pretty much right above your station, you are only talking about a coax run of about 20-feet (8-ft above earth; 8-ft ceiling; a foot or so to clear the wall/floor). That isn't a terribly long run of coax, and results should be pleasant.

From: chasm@texas.net
Topic: 2642 Message: 2652

this all bander of yours
I am not clear on the concept.
the loop is going to be one wavelength long for the lowest freq you will
transmit on? and you want two of them together a la zip cord?
you will use a tuner for the "all band" capability?

I should think that if 12 ga solid is good for 1.5kw, your 18ga should
certainly handle 500W. not sure where to find the table for that. prolly the
ARRL Antenna book<G> everything else is in there.

another question, I wonder how many loops of wire you can make around a 50x75'
lot to equal one wavelength and what the separation has to be between them? I
am still looking for a QUIET RX antenna. 75m is so bad this am I cannot copy
the NCS.

thanks

At 200W, I would think the 18ga wire should handle it just fine.....

To expand the bandwidth, you can run 2 wires in parallel.....just taping them together every so
often would not really make enough difference to be worth the effort. Spacing them apart would...how much depends on the amount of spacing between the wires. This is from my experience.....I am not even close to being an antenna expert, nor do I play one on TV (or anywhere else).

From: denisnh
Topic: 2642 Message: 2654

Hi Chas,
I know the 18g will handle 300 watts ok. What I was worried about was how it would perform, vs. the heavier gauge wires. I did a lot of googling last night to research that problem. Everything I saw indicates a thinner wire has very little effect on performance and db loss. One article I read even talked about some modeling on this issue complete with charts, and the difference between between 12g and 18g was so small that it could be considered negligible. I may have to fiddle with the tuner a little more because of the reduced bandwidth but no big deal.

For 80 meters, I will run 272' (full wave length) of wire and feed it with some homebrew ladder line made from bare 16g stranded wire that someone game me years ago. Fortunately, I have a 10' 4"x4" post at the corner of my deck, and I can run the feeder down from the loop to the top of the post (which is well away from the house) down the post, under the deck, and run that right through the sill plate into my basement ham station, which happens to be conveniently located at that spot in the basement! think that should be fine, especially conidering I don't know how much longer I'll be at this location.

What frequency on 75m will you be running? Are the dimensions you mentioned the size of your yard? You may be able to do it, but you'll be right on the boundary of your property! If I could find time, I would like to try modeling a full wave loop that takes up a half wave worth of real estate, and somehow make two turns instead of one. Could be interesting! Of course, the other option is to go with a 40m loop and use the feed line as a vertical.

Thanks,
Denis

Thanks for the response, Mel. I believe you're right, so it will be
a single 18g wire with ladder line.

Thanks,
Denis

2656. Re: Feed Arrangement for Operating the Loop as a Vertical Antenna

Yahoo group: SkyWires
Date: 2007-10-04 22:44:54 UTC
From: denisnh
Topic: 2643 Message: 2656

Thanks again, Erik! From what you wrote and the research I've done, I decided to forget about the vertical radiator and go with a full wave 18g loop and 16g homebrew ladder line (I have all this on hand). Guess I'm fickle. LOL

What I really dread is the cutting. The trees in my backyard are so dense that I'll have to get the chainsaw out and do some serious cutting. I did read about one guy who shot an arrow right over the trees with some fishing string attached, then pulled his wire right over the tops of the trees for his antenna. That scares me a bit. Not to mention that running enough power could start a fire! But it seems to work for him and he mentioned that once in a while he'll pull the wire one way or the other to compensate for any areas that are chafed through.

Thanks,
Denis

2657. Re: [SkyWires] Re: Feed Arrangement for Operating the Loop as a Vertical Antenna

Yahoo group: SkyWires
Date: 2007-10-04 23:27:37 UTC
From: Erik Weaver
Topic: 2643 Message: 2657

Hi Denis,

An atlatl is another option:

http://www.n0ew.org/k0s/atlatl/

This really seems to work well and it is pretty cheap. My friend and I didn't get up over 100-feet, but I think we got every bit of 50-feet height into the tree.

If you really want another 'project' you might think about building an air gun:

http://www.n0ew.org/k0s/air_gun/

Have fun!
Erik

Do not not worry about the performance factor OR the Bandwidth. 18ga will perform as well as 12 ga. BUT think about this:

12 ga wire is MUCH stronger than 18 ga wire. I would never use 18 ga wire for an antenna.Not strong enough ESPECIALLY if you use trees for support. I have used 16 ga for antennas. No more 16 ga for me.16 ga wire antennas don't stay up in the air.

Right now my 280 ft loop is made of 12 ga stranded soft drawn insulated thhn wire. Been up for 3 yrs and thru much wind. Very Strong. However.
12 ga wire is heavy for long spans like loop antennas It will sag. The next time I put up a loop it will be 14 ga stranded wire. It is lighter than 12 ga but still plenty strong.

Use 14 ga or bigger stranded copper wire. Use stranded open wire feeders. The antenna will stay up long after that 18 ga antenna is laying on the ground.

You may try to talk to your local power company..
Better if it is a muni company.
They may have some scrap line wire they could sell as scrap. This
would make a cheep and very strong antenna.
Most of it is not that heavy. 10 - 8 gauge. If you used strong
rope it would stay up for years and years..

I'm going just the opposite way -- I'm currently using
18-gauge Radio Shack speaker wire. Unrolled it from the spool,
separated it into two single wires, connected one end, and now I have
about 110' of wire connected to my Icom AH-4. Works pretty well, too.

I guess it's been up for a year or so. I have plans to
replace it with #12 stranded and tinned, but as with all things
"hobby" it has to wait.

Thanks for the info, Stan. I had mentioned in another post that this

stuff is designed for industrial use in hostile environments. My bro-in-law got a bunch of wire when his company went out of business and he gave some to my son and I. It was used to wire high temperature semiconductor processing furnaces.

To say it's tough is an understatement. I've used it in the past to make shortwave antennas and there is one longwire antenna which runs close to 300' I put up 3 years ago. It's still there, shows no sign of giving up, and will probably be there for years to come.

If it was the garden variety stuff from a local consumer supplier, I wouldn't use the 18g. But I have no doubt that this stuff will last a long, long time. It has no perceivable stretch to it. The wire is silver but does not look like stainless steel. It worked great for shortwave antennas.

I also have a bunch of cable/sat TV coax. I was wondering if this was run as a wire antenna, using JUST the shield, how it would work. It's pretty thick stuff, and has a heavy foil shield and braid over that. Anybody know if this would work?

Antennas like the bazooka short the coax and center conductor at various places. If I were to use just the shield as a radiator, would it be treated as a single wire conductor or would the dielectric and center conductor cause it to behave differently?

Thanks,
Denis

2662. Re: Feed Arrangement for Operating the Loop as a Vertical Antenna

Topic: 2643 Message: 2662

Hi Erik. The Atlatl looks very cool! What I've been using is a sling shot with "high powered" latex bands. A half ounce fishing sinker is then attached to some Spider Wire fishing string spooled onto a spinning reel. I have a huge pine tree that's 80' tall and I can get the line right over it with that setup. I set up an inverted-V there.

I also have an 80# pistol crossbow, and I modify the little bolt by removing the tip, placing a small weight in place of the tip and drilling a hole at the end of the shaft for the same fishing setup I mentoned above. That works even better but I don't take it out much since it looks rather ominous if the neighbors happen to get a glimpse of it.

I have some relatives in Canada, one of which owns a farm. When visiting, I like to erect a temporary antenna for use during my stay. I was surprised to find out that sling shots are illegal in that area, and the pistol crossbow is definitely illegal. I had figured a light bow but the atlatl looks very promising. As for the air gun, can you imagine the looks on the faces of the customs agents trying to get something like that across the border. Yikes!

Thanks,
Denis

2663. Re: [SkyWires] Re: Using 2 Smaller Gauge Wires in Place of Large Gauge Wires

Yahoo group: SkyWires
Date: 2007-10-06 03:14:27 UTC
From: Erik Weaver
Topic: 2642 Message: 2663

I had a 14-ga stranded copper "antenna wire" loop antenna up for about 3 or 4 years. I think I may have gotten it at The Wire Man. Or maybe Davis RF.

The antenna wire never broke. The garage door springs I used to connect it to my (3) trees broke (two of the three, a couple years apart -- garage door springs are NOT good for this use -- next time I think I'll go to the local big truck stop and get the springs the truck drivers use to keep tension on their air lines behind the cab of their tuck).

Heeheh, hi Denis,

Ya, I can easily imagine some 'lost time' trying to cross the border with various weapons. If you follow the various lists, or perhaps search their archives, you'll find many things are considered weapons, and some of those that are not required a fishing license. The guys with the guns figure if you have any fishing gear you need that permit. Or a fine. Of course, you can always come back and try arguing with a judge later on...

Arrows, crossbow (whether handheld or "industrial" strength), small pieces of lead (sinkers) moving at rapid velocities all incur a certain level of risk, if not illegality. A tennis ball on the other hand seems about as "warm and fuzzy" as we can get in this messed up PC-crazy world.

Besides, the atlatl is quite cool! Did you check out the international competitions? Neat stuff! A very old technology, assisting us with very modern technology. If only Ug and Grog had known when they invented it! :)

It is a doggie toy for throwing tennis balls. Everyone either has a dog, may be getting a dog, or visiting a friend who has a dog. So you can always carry one of these. They are just plastic, very light to carry, and even fun to play with! Buy extra tennis balls because you'll lose some just flinging them around :) My friend and I lost one or two that day, for exactly that reason!

You may want to get two of the atlatl's so you can play catch.

Have fun!
Erik
